CASE 1184.—Sergeant Foster Hudson, Co. B, 132d New York, aged 24 years, was wounded near Kinston, North Carolina, March 7, 1865. Surgeon C. A. Cowgill, U. S. V., reported from Foster Hospital, New Berne: "Admitted March 8, 1865, with a gunshot wound, shattering the tibia of the left leg and opening the knee joint. On March 9th Assistant Surgeon E. F. Hendricks, 15th Connecticut, amputated the thigh at the lower third. There was extensive shattering of the head of the tibia, and the soft parts were much infiltrated with blood and serum. The pulse was weak at the time of the operation. Simple dressings were applied to the wound and stimulants administered. The posterior flap sloughed away on the eighth day, but the interior was healthy and covered the stump. On the tenth day the ligature came away, but the stump looked well. Pulse weak, appetite poor. Twelfth day, severe chill, followed by delirium, drowsiness, and spasmodic twitching of muscles. On March 21st, hæmorrhage, amounting to one quart, occurred from the femoral artery. He died March 23, 1865, from secondary hæmorrhage, probably induced by convulsive movements of patient and stump."

The records of the war show a large number of hæmorrhages subsequent to excisions, probably due to the engorged condition of the vessels in the neighborhood of the injury which were cut or injured during such operation.

Treatment.—Of the two thousand two hundred and thirty-five cases of hæmorrhage, two hundred and ninety-four were followed by amputation; seven hundred and eighty-six were treated by compression, styptics, etc., or ceased spontaneously; and in one thousand one hundred and fifty-five cases the bleeding vessels were ligated.

TABLE CXLIX.

Summary of Two Thousand Two Hundred and Thirty-five Cases of Hæmorrhage, indicating Mode of Treatment.

TREATMENT.	CASES.	RECOVERY.	FATAL.	PERCENTAGE OF FATALITY.
Hæmorrhage followed by Amputation	294	122	172	58.5
Hæmorrhage ceased spontaneously or was arrested by Compression and Styptics	786	262	524	66.6
Hæmorrhage followed by Ligations	720	328	392	54.4
Hæmorrhage followed by Ligations and subsequent Amputation	87	34	53	60.9
Hæmorrhage from Stump after Amputation (ligated)	348	109	239	68.6
Aggregates	2,235	855	1,380	61.7

Amputation was resorted to for the purpose of saving life in cases of uncontrollable hæmorrhage, both primary and secondary: In primary bleeding, where the original injury

[1] BRINTON (J. H.), *On Amputation at the Knee Joint and at the Knee*, in *Am. Jour. Med. Sci.*, 1868, Vol. LV, p. 316.

was so far destructive to the parts as to render ligation unavailing; in secondary bleeding, in cases of traumatic aneurism, with great infiltration of tissue; in gangrene following division or ligation of the principal artery; and in cases where ligation had failed to arrest bleeding, and where more radical measures were demanded to prevent a further loss of blood. Of two hundred and ninety-four cases thus treated by amputation, one hundred and twenty-two recovered and one hundred and seventy-two died, a fatality of 58.5 per cent.

Of the remaining one thousand nine hundred and forty-one cases of hæmorrhage, seven hundred and eighty-six were treated by compression, styptics, etc. The fatality of these cases, as indicated in TABLE CXLIX, on the preceding page, was large, exceeding that of ligations 12.2 and that of ligations and subsequent amputations 5.7 per cent. In a number of cases digital compression was employed as a temporary measure, and in a few instances steadily continued compression appears to have been rewarded with favorable results. Generally the tourniquet was carefully and judiciously used, although, in a few instances, a resort to operative procedure would have been much better for the patient:

CASE 1185.—Sergeant T. A. Polleys, Co. H, 6th Wisconsin, aged 25 years, was wounded before Petersburg, June 18, 1864, by a musket ball, which fractured the right thigh. He was admitted to the field hospital of the 4th division, Fifth Corps, where amputation at the lower third of the femur was performed by Surgeon J. H. Beach, 24th Michigan, on the following day. Acting Assistant Surgeon H. E. McCartin reported the following result of the case: "The patient entered Baptist Church Hospital, at Alexandria, on June 28th. The amputation had been performed by the posterior flap method. When received into hospital the stump was found strangulated by a tourniquet placed around it to compress the femoral, and the flap was gangrenous and sloughing extensively; patient's condition very low. Tonics, stimulants, and nutritious diet failed to produce any improvement. Hæmorrhage to the amount of thirty-two ounces from the femoral artery occurred on June 28th; the patient died on June 29, 1864."

Cases of troublesome bleeding from the posterior auricular, occipital, or temporal arteries, or their branches, are reported where the hæmorrhage was controlled by compression by a clamp tourniquet, or by bandage and compress, or by a compress consisting of a metallic disk. In one such instance transverse division of the wounded artery was sufficient to secure complete retraction of the coats.

No cases of acupressure, after the method of Sir James Y. Simpson, appear on the records, though it would seem probable that many wounds must have presented themselves where this measure would have been found convenient, speedy, and effectual.

Torsion was employed to secure arteries, a few cases of this procedure being reported; and Surgeon H. S. Hewit, U. S. V., mentions a case where the actual cautery was resorted to for the arrest of troublesome bleeding.

Two cases of transfusion of blood are found on the records; one, a successful operation, was performed by Surgeon E. Bentley, U. S. V.; the other, a fatal case, by Assistant Surgeon B. E. Fryer, U. S. A. Both are here detailed:

CASE 1186.—Private G. P. Cross, Co. F, 1st Massachusetts Heavy Artillery, aged 19 years, was wounded in the right leg, before Petersburg, June 16, 1864, and entered the Grosvenor Branch Hospital, Alexandria, two weeks afterwards. Surgeon E. Bentley, U. S. V., who operated in the case, made the following report: "The injury consisted of a flesh wound on the posterior aspect of the leg. At the date of the patient's admission he was exsanguineous from previous loss of blood. Owing to his condition no operative measures were adopted, but his languishing vital powers were sustained by stimulating treatment combined with highly nutritious diet. Under this method he slightly improved in strength, but the circulating fluid was so impoverished in quality and reduced in quantity that the face of the wound looked pale and bad, and ultimately, on August 12th, it assumed a gangrenous aspect. Local applications, such as creasote, charcoal poultices, nitric acid, etc., were applied to combat this condition. These means failed to arrest its onward progress, the leg presenting in a short space of time a mass of gangrenous sloughs, horribly fetid. Hæmorrhage from the posterior tibial artery again commenced on the afternoon of August 15th, when it was deemed advisable to amputate to prevent further loss of blood. The operation was accordingly performed just at the tubercle of the tibia, the condition of the parts not allowing a flap to be made below that point. Not more than two tablespoonsful of blood was lost; but the patient not seeming to rally, it was determined to test the method of transfusion of blood as recommended by Brown-Séquard. Blood having been obtained from the temporal artery of a strong healthy German, an attempt was made to penetrate the internal saphenous vein, but was unsuccessful on account of its small size; after which an

opening was made into the median basilic, and about two ounces were transfused by means of a Tiemann's syringe. Immediately after the injection a marked difference was noticed in the patient's pulse, which became stronger and firmer. He was then removed to his bed and generous diet was administered, together with stimulants and tonics, under which treatment he gradually improved, his appetite became better, his strength increased, and the stump assumed a healthy aspect. On October 20th the stump had healed and the patient had so far improved as to be able to be furloughed. At its expiration he returned, and, finally, he was transferred to Webster Hospital, Manchester, January 13, 1865, cured." The patient was ultimately discharged from Central Park Hospital at New York City, June 9, 1865, and pensioned, and afterwards he was supplied with a "Hudson" artificial limb. This pensioner died August 24, 1867.

CASE 1187.—Private J. Mott, Co. E, 105th Illinois, aged 37 years, received a flesh wound in the upper third of the left leg, at Kenesaw Mountain, June 26, 1864, by a musket ball, which lodged between the tibia and fibula. He entered Brown Hospital, at Louisville, nine days after receiving the injury, the missile having been extracted and the wound looking unhealthy and sloughing. During the night of July 24th the patient had a copious hæmorrhage from what was supposed to be the anterior tibial artery, which was arrested. On July 26th bleeding again commenced, the blood welling up from between the bones and from the tissues posterior to them. It was then deemed necessary, in order to save life, to amputate, which was done through the upper third of the leg by the circular method, by Assistant Surgeon B. E. Fryer, U. S. A. Ether was used as an anæsthetic, and three ligatures were applied, the patient reacting very slowly. On the following day it was determined to transfuse some blood into the patient, for which purpose, in the absence of any other suitable apparatus, an ordinary gutta-percha syringe was used, the nozzle of which was filed to fit a small tube having a stop-cock through its centre. The right cephalic vein having been selected, an opening was made carefully into it, and the syringe having been warmed and filled with blood from a healthy man, a little of which was allowed to flow from the syringe before forcing its nozzle tightly into the tube in order that any air might be driven out, the tube was introduced and the stream of blood was slowly and carefully forced in. About sixteen ounces were thus transfused. The first effect upon the patient was to increase respiration from about fifteen to twenty-eight per minute, though it soon returned to its normal number of about sixteen. The pulse ran up from one hundred to one hundred and thirty, which, however, also soon returned to what it had been. The man's general condition was greatly improved. His pulse became fuller and slower; he slept well; his stomach retained food, and altogether the prognosis became more favorable. On August 4th hæmorrhage commenced from the face of the stump, the whole surface of which appeared to be involved. From the effects of this, and from chronic dysentery, the patient died on the following day, August 5, 1864; although his condition, from the effects of chronic dysentery and of the hæmorrhage at the time of the transfusion, was such as hardly to expect his recovery, the improvement was such as to show that the operation was not only justifiable, but that it was to all intents a success. The history of the case was reported by the operator.

Styptics were very commonly used. The persulphate of iron in powder or in solution was placed in every knapsack and pannier, and was found at every hospital. In addition to these we find mention of the nitrate of silver, gallic and tannic acids, alum, and turpentine as having been employed. While it is possible that in many cases the use of styptics may have been ill-advised, and while it may be admitted that in the hands of the timid or ignorant surgeon they may furnish an excuse for procrastination or for deferring operations imperatively demanded, still the evidence as to their usefulness during the late war is not altogether unfavorable, and should lead to some modification of the views previously expressed in this history. The experience of surgeons in the Confederate Army was much to the same point, and Dr. Chisolm observes that "iron styptics will control the most annoying hæmorrhage." Instances in which this class of hæmostatics was successfully used, even in bleeding from larger vessels, are not wanting:

CASE 1188.—Captain E. H. Davis, Inspector General, aged 32 years, was wounded at Fort Steadman, March 25, 1865, by shrapnel, which fractured and comminuted the bones of the right arm and forearm. Surgeon J. M. Holloway states[1] that amputation of the arm was done on the morning of the 26th, supposed to be at the anatomical neck. Repair of the wound was very rapid and unaccompanied by unpleasant symtoms other than occasional nervous twitching in stump. On April 19th he took a long walk; at that time the wound was nearly closed externally. On April 20th he experienced a tingling sensation in the arm, which was immediately followed by a gush of blood. Medical aid was speedily obtained, the dressings removed; a small clot near the lower edge of the incision was removed, and, after exposing the parts for a short time to the air, a compress was secured in the axilla by means of a roller. The patient informed me subsequently that for three days before the hæmorrhage the discharge, which before that had almost entirely ceased, increased in quantity and was darker, and accompanied by a constant aching pain in stump. From this it was concluded that ulcerative destruction of the tissues was going on, which in the end invaded the artery. Hæmorrhage recurred at 3 and again at 6 o'clock of April 21st. Upon removing the dressings, extensive extravasation of blood was discovered in the axilla and anterior thoracic region. *Diagnosis:* Indeterminate hæmorrhage from an aperture in the axillary artery, occasioned by ulcerative destruction of the coats of the artery and the newly formed tissues surrounding. April 21st, 10 A. M., pulse frequent and feeble; cheeks blanched from loss of blood; mind clear and calm; fully aware of the danger of his condition. He was placed upon the operating table, a full stimulant was given, compression with the finger and key was made in the subclavian triangle, and the careful administration of chloroform was commenced. Before

[1] HOLLOWAY (J. M.). *Consecutive and Indeterminate Hæmorrhage from Large Arteries after Gunshot Wounds, etc.*, in *American Journal Medical Sciences*, 1865, Vol. L, p. 348.

he became fully anæsthetized the dressings were removed and the cicatrix laid freely open. The opening was then enlarged by an incision at right angles to this, extending obliquely downward and inward through the skin and great pectoral muscle. A number of large clots were turned out, and, the cavity being empty, pressure upon the subclavian was removed to secure a jet of blood to guide to the bleeding point; the jet was easily obtained, and the blood welled up from the bottom of the cavity, which extended high up under the clavicle. Such was the disorganized condition of the surrounding tissues that no artery could be seen, and it was decided, without delay, that the search should not be prolonged, and that the best chance for the patient would be to plug the cavity with successive layers of lint saturated with a strong solution of persulphate of iron, well packed in, and secured by a figure-of-eight bandage. This was done. Prescribed two grains of opium and ten grains of quinine to be taken at once. April 22d: Has reacted fully; shows loss of blood; slight increase of heat in stump; slept well all yesterday and at night under the influence of the opium and quinine. April 24th, attacked with colic last evening, which was soon relieved by a large enema; annoyed also by uneasiness in the stump. Disorganized blood still exuding. On April 26th the sponge that was placed over the plugs was removed by saturating it with water, after which slight capillary oozing occurred. On April 27th he was seized with a slight rigor, followed by fever, which broke up in a short time, leaving him with a moist skin. On April 29th the largest and most superficial plug came away without force, in the evening; another at 12 P. M. The patient gradually and steadily improved until the morning of May 5th, when he was seized with severe lancinating pain in the right side, which persisted, with distressing nervous symptoms, throughout the day. Physical exploration of the chest could detect no lesion of the lung; strong suspicion of pyæmia was entertained; had suffered with severe pain in the muscles of the jaw during mastication for several days. The patient subsequently suffered from colliquative sweats; the pain and stiffness of the muscles of the jaw increased and interfered with his relish for food. On May 15th the last wad was removed, and the channel soon after closed.

The use of ice and cold was very general and was very favorably regarded. Internal hæmastatics were used to some extent, but little can be said decisively in their favor from the records of cases in which they were used. Of those most frequently used may be mentioned tannic and gallic acids and ergot, generally in the form of the fluid extract. These remedies were especially employed in cases where the vital powers were much depressed and where the coagulative elements of the blood were deficient.

Ligations.—In one thousand one hundred and fifty-five cases of hæmorrhage recourse was had to ligations, embracing nearly all the principal arterial trunks and their branches. Of these, four hundred and seventy-one recovered and six hundred and eighty-four died. The fatality in these cases, as well as in the cases of hæmorrhage followed by amputation, was principally due to exhaustion following excessive loss of blood previous to the operations, to recurring hæmorrhages after operations, or to complications, such as gangrene, erysipelas, and especially pyæmia, as indicated in TABLE CXXIV, pp. 763, 764.

Five hundred and forty-one of these operations, with two hundred and ninety-two recoveries and two hundred and forty-nine deaths, a mortality of 46.0 per cent., were performed in the upper circulatory system, and six hundred and fourteen, with four hundred and thirty-five deaths, a fatality of 70.8 per cent., in the lower circulation, thus confirming the general opinion that proximity to centre of circulation favorably influences the final issue.

Three hundred and forty-eight were ligations after amputations; of these, one hundred and fifty-seven, with fifty-two recoveries and one hundred and five deaths, were ligations in the continuity of the stump, and one hundred and ninety-one, with one hundred and thirty-four deaths, ligations on the face of the stump. It is probable that the ligation in continuity was frequently the only alternative, and perhaps a greater saving of life would have resulted had the operation been more generally performed in the continuity, as bleedings from the stump were generally found in patients of low vitality and where but little was to be expected from any operation in the immediate proximity to diseased tissue. Of the remaining eight hundred and seven cases, two hundred and thirty-six were ligations in the wound, five ligations above and below the wound, and four hundred and thirteen ligations in the continuity; in one hundred and fifty-three instances the mode of ligation was not indicated. It is probable that the large majority of ligations of the last group were operations in the continuity. The various modes of ligations with their respective mortalities are indicated in the following table:

TABLE CL.

Table indicating the various Modes of Ligations and their Fatality.

The fatality after ligations in the continuity was 63.1 per cent., after ligations in the wound 43.6 per cent. The necessity of ligating both ends has been shown in numerous instances in the preceding volumes. In the case of Lieutenant Colonel M. M. Dawson, 100th Pennsylvania Volunteers (CASE 1251, page 442, *Second Surgical Volume*), the cardiac end only of the axillary was tied for hæmorrhage occurring on the tenth day after the injury; the hæmorrhage continued, and the distal end was secured by tying the brachial. In Private G. Harbison's case (*Second Surgical Volume*, page 451) a ligature was placed on the proximal end of the ulnar artery; but hæmorrhage recurring on the next day, the distal end was ligated, and no further bleeding occurred. In the following instances of ligation of the femoral artery hæmorrhages from the distal ends occurred on the second, fourth, and sixth days after the ligation:

CASE 1189.—Private J. Sesler, Co. H, 148th New York, aged 28 years, was wounded in the left thigh, at Cold Harbor, June 3, 1864. From the field he passed to Mount Pleasant Hospital, at Washington, and thence, on June 15th, to Mower, Philadelphia. Surgeon J. Hopkinson, U. S. V., in charge of the latter, made the following report: "The injury was caused by a musket ball passing through the inner aspect of the lower third of the limb. There was profuse discharge and extensive sloughing, extending down to and ulcerating through the femoral artery, and causing hæmorrhage to the amount of from four to six ounces on July 24th, when the vessel was ligated in its continuity, at the middle third of the thigh, one inch above the wound. Bleeding recurred to the extent of from six to eight ounces from the lower end of the artery on July 28th, when the distal end of the vessel was ligated in the wound. The operations were performed by Acting Assistant Surgeon W. P. Moon, chloroform being used in the first and ether in the last, and both being followed by prompt reaction. The patient did well afterwards. The subsequent treatment consisted of simple dressings, tonics, and stimulants." The patient was discharged from service on January 11, 1865, and pensioned. Examiner R. C. Dunham, of Seneca Falls, New York, certified, August 7, 1877, to the injury, and added that the muscular structures and integuments on the inner side of the limb have sloughed out, and that the remaining structures have healed to the bone; also that "the leg is swelled below the knee and is sore and tender to the touch; knee partially anchylosed. Some important nerves must have been wounded and are healed in the structure with the cicatrix, as the leg below the wound is very numb and weak. He cannot walk but a very little distance at a time," etc. The pensioner was paid March 4, 1882.

CASE 1190.—Private C. Berkey, Co. A, 10th Pennsylvania Reserves, aged 24 years, was wounded at the battle of Manassas, August 30, 1862, and entered Filbert Street Hospital, Philadelphia, four days afterwards. Acting Assistant Surgeon A. D. Hall reported the injury as a "wound of the popliteal artery," and described the case as follows: "A round ball passed through the lower third of the left thigh, entering on the inner side one inch or so above the condyles, and making its exit at the opposite side in the direct course of the popliteal artery. The case was treated by simple dressings until the occurrence of arterial hæmorrhage on September 11th from both wounds, which amounted to about sixteen ounces, and was checked by compression with tourniquets until September 13th, when it recurred twice to the extent of eight ounces. Compression by means of Petit's tourniquet over the

femoral, Skey's below the wound, and graduated compresses over the course of the vessel proving unsuccessful, and several attacks of hæmorrhage, though small in amount, occurring on the next day, the femoral artery was ligated at 10 P. M., at the middle third of the thigh, after the method of Hunter. The ligature controlling the bleeding, all compresses were removed after the operation. On September 15th there was slight oozing of bloody serum from the old wounds, and at 11 P. M. another hæmorrhage occurred from the inner wound to the amount of three ounces, which ceased after the application of the tourniquet to the femoral where it crosses the brim of the pelvis. There was no return of hæmorrhage until the morning of September 17th, when it recurred to the amount of six ounces. The question of ligating the popliteal was now discussed, and after consultation it was decided to cut down upon the artery, upon doing which the whole popliteal space beneath the external muscles was found to be in a sloughing state and filled with broken down masses of clot and grumous matter. A cavity was formed by the sloughing tissue that dissected up the muscles of the thigh and laid bare the lower part of the femur. The bullet appeared to have grooved the under surface of the femur in its passage, producing some comminution and opening the cancellated structure of the bone. Under these circumstances it was considered that amputation, although almost certainly fatal, would afford the only chance for the patient. Ether was accordingly given, and the operation was performed by the circular method at the upper part of the middle third of the thigh. There was no reaction, the patient continuing to sink, and dying at 1 A. M. on September 18, 1862. At the *post-mortem* examination the popliteal artery was found to be opened for about one-sixth of an inch at the middle of the popliteal space, in a direction parallel to the axis of the artery. The popliteal vein was filled to distension by a firm clot. The track of the wound was found to have entered through the external hamstring tendon, channelling the under surface of the femur and emerging through the inner hamstring tendon. The popliteal artery was not obliterated, and the hæmorrhage must have occurred, after the ligation, from the lower end of the vessel through the recurrent circulation. The femoral artery was found to be ligated about four inches below the origin of the profunda, a clot extending from the point of the ligature about one-fourth of an inch up to the first small artery above."

CASE 1191.—Private M. Knecht, Co. K, 4th Ohio Cavalry, was wounded in the left thigh, July 1, 1863, by a musket ball, which entered at the lower and external side above the condyle of the femur, and made its exit at the inner condyle near the attachment of the hamstring muscle. He was admitted to hospital at Murfreesboro' nine days after the injury, where Assistant Surgeon W. P. McCullough, 78th Pennsylvania, recorded the following treatment: "The limb was bandaged from foot to hip and ice was applied to the knee. Hæmorrhage occurred on July 28th and 31st to the amount of about twenty ounces, and was controlled by compression. On August 3d there was another hæmorrhage, amounting to twelve ounces, and ligation of the popliteal artery was performed by enlarging the opening of exit. Two days later hæmorrhage again occurred from the wound, and a large anastomotic branch was tied. No further attack followed until August 9th, when profuse bleeding set in from the lower end of the wounded artery, and the femoral was ligated in the middle third. Stimulants were given freely and artificial heat was applied to the foot and leg. The patient died of exhaustion August 14, 1863." The lower third of the shaft of the femur of the injured thigh, showing the outer and posterior border of the bone to be perforated above the condyle by the missile, the seat of injury being carious, was contributed to the Museum by Surgeon I. Moses, U. S. V., and constitutes specimen 1757 of the *Surgical Section*.

Two hundred and sixty-one of four hundred and thirteen ligations in the continuity had fatal terminations, a mortality rate of 63.1 per cent., exceeding the fatality of ligations in the wound nearly 20 per cent.; but it will be observed that, with the exception of the femoral, the large vessels, as the carotid, subclavian, axillary, iliac, and popliteal arteries were, as a rule, tied in the continuity. It is to be regretted that ligations of both ends in the wound were not more generally practiced.

Lidell records,[1] as his personal observation after several severe battles, that he had not met "with a single case of primary hæmorrhage which required a surgical operation, such as the application of a ligature for its suppression." Neudörfer and Richter,[2] experienced European military surgeons, have never been called upon to control primary hæmorrhage after injuries of blood-vessels by ligature on the battle-field or the first place of dressing. But a number of such operations were performed during the war of the rebellion, and the results of these operations seem to have been quite successful. Thus, for instance, of thirteen ligations of the femoral performed on the battle-field, seven proved successful; of ten ligations of the tibial arteries, seven terminated in recovery; and of fourteen ligations of the brachial only one had a fatal termination, although several of these cases were complicated by fractures. In the case of A. Elmer, 69th Pennsylvania (CASE 679, page 435, *ante*), the tibia was fractured and the anterior tibial artery divided; the latter was secured by a ligature on the field; the patient recovered. A case of shot fracture of the lower third

of the left femur, in which the femoral artery was severed and successfully ligated on the field, is cited in TABLE XLIX, on page 353, *ante*, CASE 2.

VEINS.—Hæmorrhage from wounded veins is generally regarded as of less practical importance than that from wounded arteries. It is stated in a previous portion of the history that "no cases have been reported in which the bleeding could not be controlled by pressure." An examination of the cases in the following table shows that in five instances at least ligation of veins was resorted to:

Among the instances of wounds of the arteries considered in the preceding pages were quite a number in which the veins were likewise injured. These cases have not been included in this statement of one hundred and six (106) venous hæmorrhages, of which eighty-six (86), or 81.1 per cent., proved fatal.

From the number of venous vessels, and from the fact that they are less liable to evade a projectile in its course than the arteries, it would seem that injuries and hæmorrhages of the veins should have been more frequently noted. Statistics on the relative frequency of injuries of the arteries and veins are nowhere found in military surgery. Richter[1] suspects that many soldiers perish on the battle-field from injuries of these vessels. It remains a fact, however, that hæmorrhages from veins come far more rarely under the observation of the surgeon than those of arteries; but that their fatality is equally as great, if not greater, than that of arteries, is clearly proven in the above tabular statement.

Wounds of large veins lying in cavities and beyond the reach of ligation seem to be as

[1] RICHTER (E.), *Chir. der Schussverletzungen im Kriege mit besonderer Berücksichtigung Kriegschir. Statistik*, Breslau, 1877, 1 Theil, p. 357.

fatal as those of arteries. The femoral and jugular veins would appear to be less amenable to treatment than others which yield to pressure or cease spontaneously. In forty-seven (54.6 per cent.) of the eighty-six fatal cases, death was ascribed to secondary hæmorrhage occurring at various dates; next in order we find pyæmia and gangrene as causes of death, especially in wounds of the lower extremities.

Among the one hundred and six cases of hæmorrhage from veins were twenty cases of primary injury. Of these fifteen, or 75 per cent., were followed by primary bleeding, while in the arteries only one hundred and ten of four hundred and eighty-five, or 22.7 per cent., were succeeded by immediate hæmorrhage. Secondary hæmorrhage from veins occurred at irregular intervals from one to seventy days; in one instance the bleeding did not take place until the one hundred and thirty-seventh day; and in another, a case of shot wound of the buttock, uncontrollable venous hæmorrhage occurred from a persistent fistula three years after the injury:

CASE 1192.—Private W. H. Marsh, Co. K, 13th Illinois, aged 23 years, was wounded at Chickasaw Bayou, December 29, 1862, by two musket balls, one entering the upper part of the left thigh and the other passing into the hip. He was taken prisoner and remained for a time in the hands of the enemy. In May, following, he was conveyed to Memphis, where he entered Overton Hospital, and remained for four weeks, after which he was transferred to Lawson Hospital, at St. Louis. Surgeon C. T. Alexander, U. S. A., in charge of the latter, reported that "the wound of the thigh, which is now quite healed, was treated by a Confederate physician as a fracture of the femur, which does not seem to have existed. The patient avers that the other ball, which entered the gluteal region close to the tuberosity of the ischium, is still there, though it cannot be felt by the probe. There is a sinus, however, extending six inches into the muscles of the buttock, and from the nature of the discharge it is probable that there is a foreign body of some kind in the wound." Acting Assistant Surgeon F. K. Bailey reported the subsequent history of the case, as follows: "The patient was admitted to hospital at Quincy on July 17th, being very feeble and pale and appearing to have lost a great deal of blood. He could not stand on his left lower extremity, and pus was still escaping from the orifice, which was near the coccyx. Good nourishment and laxatives, when necessary, were given, with morphia *pro re nata*. Solution of morphia was also used in poultices and dressing. Two months after his admission he complained of pain in the hypogastric when passing urine, in connection with which he stated that while he was at Vicksburg it was necessary to use the catheter. In October he had neuralgic pains in the left side of the pelvis and in the thigh, and there were indications of miasmatic chills; wound still discharging freely. Quinine was then prescribed, and subsequently small doses of strychnine were added. On October 27th a probe was passed into the opening at the ischiatic region to the depth of three inches toward a point one inch above the crest of the ilium. There was still free discharge of pus, but the patient felt much better than he did a month previously. On October 29th tincture of iodine was injected into the wound, subsequent to which he complained of severe pain along the track of the fistulous opening, accompanied by spasmodic jerking of the wounded extremity. On November 1st a small piece of woollen cloth came out of the opening, which was followed by another, one and one-half inches square, the next day. By November 15th the wound had nearly healed, very little pus was escaping, and the patient was improving in strength but could not yet step upon the injured limb. On November 24th he had some fever, with dysuria, when sweet spirits of nitre was ordered in addition to the quinine. About December 1st the patient was able to step a little and was improving finely. During the next month no change occurred in the condition of the patient, who still complained of pain in the affected side from the orifice through to the crest of the ilium, and also in the inguinal region; pus still escaping, and occasionally a shred of clothing. By March 18, 1864, a probe could still be passed in the direction of the crest of the ilium. On June 6, 1864, the patient was discharged from service for disability, being barely able to walk with the aid of a cane, and his wound not having healed." The ultimate result of the case was communicated by Dr. Bailey several years later: "In November, 1865, I returned to my former home in Joliet, Illinois, where I was called upon to examine the patient, who had returned there after receiving his discharge. The fistulous opening of his wound, which for a long time had been an exit for pus, had become gangrenous during the previous month, and about November 10th inflammation began to extend to the peritoneum, involving the bladder and causing characteristic symptoms of peritoneal inflammation through the lower part of the abdomen. Extensive venous hæmorrhage occurred about twenty-four hours before death. There was no *post-mortem* examination held." The records of the Pension Office show that death took place on November 20, 1865.

In the next two cases death was ascribed to the sudden entrance of air into the veins:

CASE 1193.—Corporal A. M. Delano, Co. E, 1st Maine Heavy Artillery, aged 21 years, was wounded at Spottsylvania, May 12, 1864, by a minié ball, which entered just back of the left ear, fracturing the mastoid process of the left temporal bone, passed downward and forward and lodged just anterior to the artery at the angle of the lower jaw. On May 22d he was admitted into Emory Hospital, Washington, where, on the same day, the missile and a fragment of the cranium were removed. On May 25th hæmorrhage to the extent of twenty ounces occurred from the internal jugular vein. He died suddenly on May 25, 1864. Air was supposed to have passed into the vein. The autopsy revealed the jugular vein to be in process of ulceration two inches of its length, with its tissues severed from before backward, except a few fibres on its posterior surface. Surgeon N. R. Moseley, U. S. V., reports the case.

CASE 1194.—Private B. F. Brown, Co. C, 22d Massachusetts, aged 23 years, was admitted into Emory Hospital, Washington, May 13, 1864, with gunshot wounds of the thigh, leg, and neck, received at the battle of the Wilderness, May 7,

1864. The thigh had been amputated on the field on May 7th, in the lower third, by lateral flaps. A ball had entered the neck below the angle of the jaw, passed through the larynx, and lodged near where the carotid crosses the omo-hyoid muscles. On May 16th the ball was extracted from its position against the carotid by an incision one and a half inches long, one inch below the mastoid process of the temporal bone, by Acting Assistant Surgeon W. H. Ensign, U. S. A. At this date the thigh was healing kindly by first intention. The wound of the neck had an extraordinary appearance. The patient's constitution was slender but not much impaired. Some trouble in swallowing and breathing; cheerful, sleeps well, shows little signs of distress; pulse 90, bowels regular. No medicine given; but good liquid diet with local water dressings. Food has to be administered with a stomach pump. On May 17th hæmorrhage to the amount of one quart occurred from the internal jugular vein. Air was supposed to have passed through the vein into the heart. A *post-mortem* examination showed the cause of hæmorrhage to be ulceration of the anterior surface of the internal jugular vein. The case is reported by Surgeon N. R. Moseley, U. S. V.

In a third instance (Case of E. C. Melley, page 555, *First Surgical Volume*) the subclavian vein was accidentally cut while searching for the axillary artery. The entrance of air caused syncope, and death ensued in less than ten minutes.

In the accompanying chromo-lithograph (PLATE LXXIX, FIG. I) the appearance of the femoral vein removed from a stump twelve hours after death from pyæmia (Case of Sailor, No. 469, page 289, *ante*) is faithfully represented. The end of the vein, well sealed up in the stump, was empty, and collapsed from the end up to the valve of the first anastomosing branch, a distance of about six inches. The vein in this situation was about as large as the artery, the walls being much thickened and about the thickness of those of the artery; the lining membrane looked velvety, wrinkled, and dirty-gray in color; there was no pus in the vein. From the valve above mentioned up to the mouth of the vena profunda, a distance of about two and a half inches, the femoral vein was filled to distension with fetid broken-down liquefied blood, its lining membrane dirty-gray colored in this situation, and its walls somewhat thicker than natural; no pus was found in this locality by the microscope. At the mouth of the vena profunda the femoral vein was plugged up with yellowish-white fibrine; the vena profunda and many of its branches were filled and knotted with recent coagulum; the femoral vein was also filled with recent coagulum above the mouth of the profunda to a distance of about two and a half inches; the lining membrane of the profunda and of the part of the femoral vein last mentioned were stained dark red, and the walls of the vessels somewhat thickened in the same locality. A thin dark colored recent coagulum, not filling the calibre, extended the whole length of the external iliac vein.

TETANUS.

Considering the number of injuries, the proportion of cases of tetanus is not large; of the two hundred and forty-six thousand seven hundred and twelve (246,712) injuries by weapons of war, five hundred and five (0.20 per cent., or a little over two in a thousand) were followed by tetanus. In the cases in which this complication was observed the seat of the injury was: in the head, face, and neck in twenty-one instances, in the trunk in fifty-five, in the upper extremities in one hundred and thirty-seven, in the lower extremities in two hundred and ninety-two instances. The preponderating frequency of tetanus in the lower extremities, observed by Beck[1] and others, was very marked, over one-half of all the cases having occurred after injuries in this portion of the human structure, due undoubtedly to the massive layers of muscles and soft tissue, which prevent the surgeon frequently from clearing the track of the wound of foreign bodies and other obnoxious influences. Of the two hundred and ninety-two cases of tetanus in the lower extremities, the injuries were in the hip in two instances, in the thigh in ninety-nine, in the knee in seventeen, in the leg in ninety-five, in the ankle in twenty-two, and in the foot in fifty-seven instances; of the one hundred and thirty-seven instances in the upper extremities the injuries were in the hand

in thirty-seven, in the arm in thirty-four, in the shoulder in thirty-one, in the forearm in twenty-four, in the elbow in seven, and in the wrist in four instances. The belief that shot wounds of the foot and hand are particularly apt to cause tetanus is not confirmed by the cases recorded during the war. In the lower extremity, especially, this complication is found most frequently in injuries of the thigh and the leg. In one hundred and thirty-one instances tetanus followed closely upon operations in the extremities, viz, in one hundred and sixteen cases after amputations and in fifteen cases after excisions. The rarity of tetanus as a complication of chest wounds has been noted on page 635 of the *First Surgical Volume*, and it may here be added that in all but one of the seventeen cases there referred to the complication was due to simultaneous injuries of the scapula, shoulder joint, or arm.

Of the five hundred and five cases, four hundred and fifty-one, or 89.3 per cent., ended in death, as follows:

TABLE CLII.

Summary of Five Hundred and Five Cases of Tetanus, indicating Seat of Injury and Result.

SEAT OF INJURY.	TOTAL CASES.	RECOVERIES.	DEATHS.	RATIO OF MORTALITY.
Head, Face, Neck	21	1	20	95.2
Trunk	55	5	50	90.9
Upper Extremity	137	18	119	86.8
Lower Extremity	292	30	262	89.7
Aggregates	505	54	451	89.3

The recoveries after tetanus appear to have chiefly occurred in the cases of slighter or tetanoid forms, or in those in which the disease took a chronic course, and it is possible that the early application of powerful narcotics interrupted the progress of the malady in a few cases of acute form. From an examination of these cases it may be concluded that the later the occurrence of the disease after an injury, the better was the chance of recovery; and also, that the longer the duration of the affection after its inception, the greater was the chance of life. (See TABLE CLIV, on page 820.)

In the following table are indicated the days after the injury or after amputation on which tetanus made its first appearance:

TABLE CLIII.

Statement indicating the day after Injury or Amputation on which Tetanus appeared.

	Days after the Injury or Amputation on which Tetanus appeared.																									
Cases.	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26 to 30	Above 30

In twenty-seven cases tetanus appeared on the first day; but twenty-one of these were cases of tetanus following amputations, so that in reality it only appeared in six cases within the first twenty-four hours after the original injury, and it may here be stated that, with the exception of a small number of cases, tetanus in cases of amputations invariably followed within a few days after the operation. Few cases occurred on the second, third, and fourth days after the injury; but from the fifth day, when sufficient time had elapsed for inflammatory action to establish itself, the number of cases rapidly increases until the

eighth, when it gradually diminishes again until the fourteenth, after which period tetanus appear irregularly, in one instance the malady not making its appearance until seven months after the injury.

As the causes of this fatal malady are cited: excessive heat, exposure to cold and damp air, draughts, neglect of thorough and early cleaning of the wound channel, pressure of missiles and bone splinters and of bandages on nerves, injuries to nerves while searching for foreign bodies or while performing ligations and excisions.

The duration of the disease is indicated in three hundred and fifty-eight cases, of which twenty-one ended in recovery and three hundred and thirty-seven in death, as follows:

TABLE CLIV.

Numerical Statement of Results of Three Hundred and Fifty-eight Cases of Tetanus in which the duration of the disease was reported.

RESULT.	Totals.	Days of Duration of Tetanus.																												
		1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	18	19	20	21	23	24	26	27	29	33	37	39	48	49

	358	70	84	49	31	22	19	14	7	6	7	9	3	2	5	4	1	4	1	4	4	2	1	1	2	1	1	1	1	1	1

In two hundred and three, or more than one-half of the cases in which this point was ascertained, the duration of the malady did not exceed three days, and of these only two recovered; in the remaining nineteen cases of recovery the disease lasted from nine to forty-nine days, while the longest duration in the fatal cases was only twenty-seven days.

In several cases the removal of the missile or of foreign bodies, as pieces of bone, seem to have quieted the threatening symptoms; in one instance they were relieved by the loosening of a bandage pressing on the brachial plexus, and in another by the removal of a neuroma:

CASE 1195.—Private Oscar C. Romaine, Co. I, 145th New York, aged 20 years, was wounded in the right index finger October 25, 1862. The finger was amputated near the base of the first phalanx on October 30th. The part healed readily, but was very tender and often painful. In this condition he was admitted into Lincoln Hospital, Washington, January 18, 1863. Acting Assistant Surgeon B. P. Brown reported: "Nothing special transpired until March 20th, when, on attempting to swallow, he was seized with pain and stiffness in the neck and was unable to speak. Soon there was a heaving up of the chest and the head was rapidly thrown from side to side; the jaws closed, the angles of the mouth were drawn back, the eyebrows knit, and the countenance of a ghastly appearance. For a moment there would be partial remission, when the patient would complain that he could not bear to have any one touch him, as it caused the most severe suffering. Suddenly another paroxysm would come on more severe than the former, and then an interval, which, however, would be very short. This state of things continued from four o'clock P. M. till one o'clock A. M., when it was decided upon to open the wound and search for the cause. The part being laid open, a neuroma somewhat larger than a buckshot was found intimately incorporated with the hard cicatrix and tightly adherent to a spiculum of bone beneath. The tumor was removed, also the bony portion to which it had been attached. The parts were then brought together by adhesive straps, and the patient rested well, having but one more spasm about four o'clock A. M., and that very light. He is now quite recovered and enjoying better health than for some months past." He was discharged from service June 19, 1863. He is not a pensioner.

In the following case an incision down to the nerve temporarily relieved the symptoms of trismus, caused by the contraction of the cicatrix. As the symptoms reappeared with increased vehemence, a portion of the nerve was dissected out, and, no relief being afforded, amputation remained the only alternative:

CASE 1196.—Private John C. Marks, Co. D, 149th Pennsylvania, aged 28 years, was wounded at the Wilderness, May 10, 1864. On May 13th he was admitted into Stanton Hospital, Washington, whence Surgeon John A. Lidell, U. S. V., reported: "Flesh wounds of both arms by a musket ball, which, after passing through the left arm, entered the right near the inner edge of the biceps muscle, and passed through obliquely, outward and downward. At the end of about six weeks both wounds had healed; the cicatrix was firm. The medial nerve was evidently included in the cicatrix of the wound of the right arm, as he suffered intense pain in the course of it, especially in the fingers, which were stiff and extended. The nutrition of the arm

was also impaired. He suffered great nervous irritation. September 16th, the pain in the forearm and hand is very severe; he has also partial trismus; his jaws are stiff, but he can open them to the extent of about an inch. He has failed in strength and appetite and is emaciated." Dr. Lidell made an incision about two inches in length through the cicatrix down to the nerve, which was loosened and laid bare to the extent of the incision. The old cicatrix was also removed. The nerve did not appear to be injured in any way. The pain was apparently caused by compression of it—by the contraction of the cicatrix. The wound was left open to heal by granulation. He had been treated to date of operation by subcutaneous injections of morphia, which relieved the pain temporarily. September 17th, pain is slight, trismus lessened; passed a comfortable night. September 18th, pain continues, trismus subsided. The injections of morphia were continued at night, and a grain of sulphate of zinc ordered thrice daily. September 30th, treatment continued to date. The operation has only afforded partial relief. The pain continues quite severe. October 6th, the wound of the previous operation has entirely healed, but he cannot use the hand in consequence of the exalted sensibility of it; the pain in it is very severe, and he is suffering much from want of sleep. He has had several paroxysms of severe tetanic irritation, with some stiffness of the jaws, one of which occurred this morning. Assistant Surgeon George A. Mursick, U. S. V., made an incision through the cicatrix of the previous operation and dissected out the median and excutaneous nerves, which were found lying in close apposition, and resected three-fourths of an inch of each of them. They were both involved in the new cicatrix. October 19th, the operation of resection did not avail anything, and his condition is as bad as ever. The pain is now so severe as to deprive him of all rest, and the sensibility of the hand is so great that he will not allow anything to touch it. His general health is suffering severely. His countenance expresses great anxiety and his appetite has failed. Surgeon John A. Lidell, U. S. V., administered chloroform and amputated the right arm at the junction of the upper with the middle third by anteror posterior flaps. Marks recovered, and was discharged May 27, 1865, and pensioned.

Including the case just detailed, amputation was resorted to in twenty-nine instances after incipient tetanic symptoms; ten of the cases resulted favorably, and in several instances it is noted that the symptoms ceased after the operation. A few of these cases are here cited in detail:

CASE 1197.—Private D. E. Isham, Co. E, 154th New York, aged 19 years, was wounded in the left foot, at Chancellorsville, May 3, 1863, and was admitted to a field hospital of the Second Corps. Surgeon C. S. Wood, 66th New York, made the following report: "The injury was caused by the explosion of a shell, which carried away most of the foot and shattered the cuneiform bone and the astragalus, leaving the foot hanging by the integument of the plantar surface. There was but little hæmorrhage, but the shock was excessive and tetanic symptoms were present; in other words the case admitted of no delay. If I remember right the patient had lain out all night. Not knowing the extent of the injury I performed Chopart's amputation, but discovering the cuneiform and astragalus bones to be so much injured I proceeded, while the patient was still under chloroform, to perform Syme's operation." The patient was subsequently transferred to hospital at Alexandria, and later to Washington, where he was discharged from service January 22, 1864, and pensioned.

CASE 1198.—Sergeant T. Lewis, Co. E, 5th Michigan, aged 26 years, was wounded in the right forearm, at Gettysburg, July 2, 1863, by a round ball, which entered on the ulmar side just above the styloid process, passed obliquely across, and came out on the radial side about two inches above the joint, comminuting both bones in its course. He was admitted to Broad and Cherry Streets Hospital, Philadelphia, July 13th, at which time his general health was not very good, the wound being inflamed and very painful. Several fragments of bone were removed, flaxseed poultice was applied, and the forearm was placed in Bond's splint. Under a treatment of tonics, with opium at night, the patient slowly improved until August 25th, when he was suddenly seized with a chill followed by threatening tetanus. In consultation the next day it was decided to amputate the forearm as a means of saving life. The operation was performed by Teal's method, at the middle third, by Acting Assistant Surgeon A. Hewson, while the patient was under the influence of ether. He reacted readily. The stump was dressed with solution of lead and laudanum, being slightly elevated on a pillow. The wound granulated rapidly, and by September 20th cicatrization was almost complete, leaving a good stump without adhesion of flaps to the bones. A slight exfoliation from the end of the radius occurred during the progress of the case. The carpus and amputated portions of the bones of the forearm were forwarded to the Museum, with the history of the case, by Acting Assistant Surgeon W. F. Keating, and constitute specimen 2794 of the *Surgical Section*. The patient was subsequently transferred to Mower Hospital, where he was discharged from service April 20, 1864, and pensioned.

CASE 1199.—Corporal P. Nelson, Co. K, 139th Pennsylvania, aged 19 years, was wounded at the Wilderness, May 5, 1864, by a musket ball, which shattered the radius and ulna of the right forearm for two inches at the junction of the middle and lower thirds, also wounding the ulnar nerve. One week after receiving the injury the man entered Finley Hospital, Washington, where he did well until June 9th, when the arm became much swollen and symptoms of tetanus ensued, including stiffening of the jaws, great pain and restlessness, and irritable pulse. On June 11th circular amputation of the arm at the middle third was performed under chloroform by Acting Assistant Surgeon D. P. Wolhaupter. All symptoms of tetanus disappeared after the operation and the patient rapidly recovered. He was ultimately discharged from service July 27, 1865, and pensioned. The two lower thirds of the bones of the fractured forearm were contributed, with the history of the case, to the Museum by Surgeon G. L. Pancoast, U. S. V., and constitute specimen 2586 of the *Surgical Section*.

CASE 1200.—Sergeant A. Smith, Co. G, 66th New York, aged 47 years, was wounded at Fredericksburg, December 11, 1862, by a shell which carried away a large portion of the right foot. Partial amputation of the foot was performed in the field by Surgeon C. S. Wood, 63th New York. The peculiarities in the case were that symptoms of tetanus were quite marked, with great exhaustion, and that relief was afforded temporarily by chloroform, and permanently by the amputation. The patient continued to do well afterwards. He was discharged from service May 1, 1863, and pensioned. The history of the case was reported by the operator.

CASE 1201.—Captain F. Schaefer, Co. I, 73d Pennsylvania, aged 26 years, was wounded at Mission Ridge, November 25, 1863, by a musket ball, which fractured the left foot and lodged. The missile was extracted the fifth day after the injury, which was followed by extensive inflammation. On December 9th symptoms of tetanus ensued, which were relieved by active purgatives, calomel, etc. Three days later the symptoms returned, and on December 13th tetanus supervened in its usual form. On December 18th the leg was amputated at the middle third, after which the tetanus subsided and the patient made a rapid and good recovery. Surgeon B. L. Hovey, 136th New York, who performed the operation, reported: "I believe, with other surgeons, that amputation cured this man of tetanus." Captain Schaefer resigned the service July 5, 1864, and subsequently became a pensioner.

CASE 1202.—Sergeant J. Henderson, Co. A, 125th New York, aged 29 years, was wounded in the right knee, at Spottsylvania, May 10, 1864, by a musket ball, which shattered the head of the fibula and the posterior surface of the tibia, lodging between the gastrocnemius and soleus muscles. He was admitted to Finley Hospital, Washington, two weeks after the injury, the wound appearing healthy and his general condition being good. A day or two afterwards the patient complained of soreness in the throat, and on May 29th marked symptoms of tetanus, such as rigidity of the muscles of the jaw and difficulty of mastication and deglutition, existed. On May 30th circular amputation at the lower third of the thigh was performed by Acting Assistant Surgeon F. G. H. Bradford, immediate relief seeming to be afforded by the operation. The following day the rigidity of the muscles had partly disappeared and improvement continued until the patient was entirely relieved. Further progress in every respect continued favorable and the stump healed. The probable cause of the appearance of tetanus was owing to a slight laceration of the external popliteal nerve, produced by the ball in its passage through the limb. On August 1, 1865, the patient was discharged from service and pensioned, having been previously fitted with a "Jewett" artificial limb. The upper portion of the bones of the amputated leg, showing the seat and extent of the injury, were contributed to the Museum, with the history of the case, by the operator.

CASE 1203.—Corporal H. Kampp, Co. A, 113th Illinois, aged 20 years, was wounded in the right forearm, before Vicksburg, May 19, 1863. He was conveyed to hospital at Memphis, and subsequently to St. Louis, where he entered Lawson Hospital one month after the date of the injury. Surgeon C. T. Alexander, U. S. A., in charge of the latter, made the following report: "The injury consisted of a compound fracture of the radius and ulna near the wrist, and was produced by a conical ball. Both bones were necrosed, and the wound was in a very bad condition at the time of the patient's admission. Numerous pieces of bone were impacted into the surrounding fleshy tissue, and pus of a fetid and unhealthy character was flowing from both wounds very abundantly. According to the patient's statement he was first taken with trismus about a week before his admission here, while he was in hospital at Memphis, though it did not appear that he had been exposed to anything unusual. As he was certainly getting worse every day it was decided to amputate as a last resort. Accordingly, on June 28th, the operation was performed about four inches below the elbow joint, the patient seeming to stand the shock very well and to gradually improve from that time. The treatment at first had consisted of a narrow blister applied along the whole length of the spine on each side, brandy and chloroform being administered every two hours. These last two remedies not appearing to do any good, one-half drachm of tincture of cannabis indica was tried every two hours, under which the patient slowly improved. An enema of beef tea and quinine had also been given three times a day from the first." The patient entirely recovered, and was discharged from service September 1, 1863, and pensioned.

The treatment of this affection was empirical to the last degree, and the formidable list of remedial agents employed in combating it presents a curious study of the diverse pathological and therapeutical views entertained by the medical profession on this subject. In the cases of recovery it is impossible to say how far any individual or class of therapeutical remedies was of avail. Chloroform, ether, opiates, stimulants, and external irritants, embrocations and fomentations, were mainly relied upon. In some instances the symptoms disappeared so speedily and permanently as to raise the question whether the same result might not have occurred spontaneously. In the fully developed cases all remedial measures failed and the cases ran on unchecked to a fatal termination. The following are the remedies which are recorded to have been used by the medical officers: Tincture of valerian, bromide of potassium, extract of cannabis indica, yellow jasmine, woorara, extract of nux vomica, tincture of aconite, assafœtida, belladonna, chlorodyn, conium, strychnia, solution of permanganate of potassa, hyoscyamus, chlorate of potassa, tartrate of antimony, Hoffmann's anodyne, chloric ether, chloroform, camphor, quinine, hyposulphites of soda and lime, nitric acid, mercurialization, castor oil, turpentine, and croton oil; stimulants and opiates were given with all of these preparations. Of external applications the following were used: Blisters, emollient poultices, warm fomentations, turpentine, ice, olive oil, creasote, warm baths, electric currents, chloroform liniment, powdered lime and opium poultice, vapor baths, powdered morphia locally, snow and salt bagged and applied to seat of injury, hyoscyamus ointment, and saturated solution of chlorate of potassa in wound.

Injections were given of sulphate of atropia and sulphate of morphia hypodermically, opiates, tobacco, turpentine, castor oil, soap and water, milk of assafœtida, vinegar, and brandy.

In the Army Medical Museum is preserved a specimen (No. 3538, *Surgical Section*) showing a shot laceration of the crural nerve in a patient who survived the injury twenty-five days and died of tetanus. The specimen and its history were contributed by Dr. William Thomson. On page 339 of the *Second Surgical Volume* a drawing illustrating its pathological histology was promised, but a careful microscopical examination of the specimen failed to indicate any abnormal conditions:

CASE 1204.—Private Alexander Fletcher, Co. F, 31st Maine, aged 21 years, was wounded at the Wilderness May 6, 1864. He was removed to the field hospital of the 2d division, Ninth Army Corps, and was transferred on May 12th to Douglas Hospital, Washington. Assistant Surgeon W. Thomson, U. S. A., reported: "Gunshot flesh wounds of left arm, and side over lower ribs. On May 20th tetanus in the form both of trismus and opisthotonos appeared. Equal quantities of laudanum and tincture of valerian were given in teaspoonful doses every two hours, which alleviated the symptoms somewhat. Death resulted on May 31, 1864, from tetanus. At the autopsy it was found that the ball had entered over the lower ribs and passed down between the muscles of the abdomen over Poupart's ligament and under the femoral vessels, wounded the crural nerve, and lodged near the middle third of the femur." The specimen of the lacerated crural nerve was contributed to the Army Medical Museum by Dr. Thomson, and is numbered 3538 of the *Surgical Section*.

In crowded field and general hospitals neither time nor opportunity was found for microscopical examination of minute structural changes, and the *post-mortem* examinations are therefore incomplete and give only negative results; no anatomical lesions of the medulla oblongata, the cerebellum, or the spinal cord in such cases were noted.

Sixteen, or 3.1 per cent., of the five hundred and five instances of tetanus were found among the colored troops, who furnished 2.7 per cent. of the total number of shot injuries.

GANGRENE.

"The necessity of the careful definition of such terms as mortification, gangrene, sphacelus, dry gangrene, moist gangrene, hospital gangrene, and gangrenous phagedæna," urged by Joseph Jones in his article on hospital gangrene,[1] has become apparent from the examination of the reports of cases of gangrene recorded during the war. According to the conception or predilection of the surgeon, these terms, in many instances, seem to have been used indiscriminately, and it has been found utterly impossible to determine with accuracy the cases of traumatic gangrene, hospital gangrene, dry gangrene, etc. For instance, there were reported, as will be shown hereafter, eight hundred and forty-six (846) cases of gangrene during the years 1862 and 1863, of which, on the hospital records, only one hundred (100) were designated as hospital gangrene, and yet Surgeon M. Goldsmith, U. S. V., in his special report on the subject, in the spring of 1863, gives a tabular statement of three hundred and forty-three (343) cases of hospital gangrene observed in the hospitals of Louisville alone during only parts of the years 1862 and 1863. An attempt to separate the various forms of this disease according to the descriptions of symptoms and treatment noted in each case failed, and it has therefore been deemed advisable to include in one tabular statement all cases of gangrene observed after shot wounds and to illustrate the various forms by examples or special reports.

The total number of cases of gangrene reported was two thousand six hundred and forty-two (2,642). Of these, sixty (60) were observed after wounds of the head, two hundred and sixteen (216) after wounds of the trunk, and two thousand three hundred and sixty-six (2,366) after wounds of the extremities, as follows:

[1] JONES (JOSEPH), *Investigations upon the Nature, Causes, and Treatment of Hospital Gangrene as it prevailed in the Confederate Armies*, 1861–1865, in *United States Sanitary Commission Memoirs*, New York, 1871, Second Surgical Volume, p. 174.

TABLE CLV.

Summary of Two Thousand Six Hundred and Forty-two Cases of Gangrene, indicating the Result and Relative Frequency.

SEAT OF INJURY.	RECOVERY.	FATAL.	UNDETERMINED.	TOTAL.	PER CENT. OF FATALITY.	PER CENT. OF RELATIVE FREQUENCY.
Flesh Wounds of Head, Face, and Neck	5	7	.....	12	58.3	... 60=2.2%
Fractures and Penetrating Wounds of Head, Face, and Neck	32	16	.....	48	33.3	
Flesh Wounds of Trunk	36	32	7	75	47.0	...216=8.2%
Fractures and Penetrating Wounds of Trunk	44	97	.....	141	68.7	
Flesh Wounds of the Upper Extremities	47	50	12	109	51.5	2,366=89.6%
Fractures of the Upper Extremities	476	245	14	735	33.9	
Flesh Wounds of the Lower Extremities	125	127	92	344	50.3	
Fractures of the Lower Extremities	596	568	14	1,178	48.7	
Aggregates	1,361	1,142	139	2,642	45.6	

Thus it will appear that 89.6 per cent. of all the cases of gangrene were observed in wounds of the extremities, 8.2 per cent. in wounds of the trunk, and only 2.2 per cent. in wounds of the head, face, and neck, although the proportion of injuries of the three regions, as shown in TABLE CXIX, page 691, *ante*, is 70.86 per cent. for the extremities, 18.37 per cent. for the trunk, and 10.77 per cent. for the head, face, and neck. Nearly two-thirds—one thousand five hundred and twenty-two (1,522)—of two thousand three hundred and sixty-six (2,366) cases of gangrene in the extremities occurred in the lower extremities, while, as has been shown before, the total number of injuries of the upper extremities slightly exceeded that of the lower extremities.

The results in one hundred and thirty-nine (139) of the two thousand six hundred and forty-two (2,642) cases of gangrene were not ascertained; one thousand three hundred and sixty-one (1,361) terminated in recovery, and one thousand one hundred and forty-two (1,142) in death, a mortality rate of 45.6 per cent.; but in a large number of these cases death was ascribed either to the injury itself or to other complications—such as pyæmia in one hundred and fifty-two (152), hæmorrhage in forty-seven (47), exhaustion in one hundred and eight (108), tetanus in eleven (11), erysipelas in two (2), and pneumonia, typhoid fever, diarrhœa, and other diseases in seventy-seven (77) instances. In three hundred and thirty-nine (339) cases the immediate cause of death was not stated. In four hundred and six (406) of the one thousand one hundred and forty-two (1,142) deaths the fatal issue was directly ascribed to gangrene. A peculiar feature in the above table is the fact that with the exception of the penetrating wounds of the trunk the percentage of fatality of the cases of gangrene after flesh wounds is larger than that after fractures. The death rate of the cases of flesh wounds of the head, face, and neck complicated by gangrene is 58.3 per cent., while that of the fractures is only 33.3 per cent.; likewise the death rate of the flesh wounds of the upper extremities attacked with gangrene is 51.5 per cent., while that of the fractures complicated with gangrene is only 33.9 per cent. In the lower extremities the mortality after gangrenous flesh wounds is 50.3, while that of the fractures is 48.7 per cent. In wounds of the trunk alone the mortality of the fractures and penetrations exceeds that of the flesh wounds, the former being 68.7, the latter 47.0 per cent.

Of the two thousand three hundred and sixty-six (2,366) instances of gangrene in the extremities, one hundred and eighty-five (185) were cases of gangrene following excisions, and in forty-six (46) of these cases amputation of the limb had to be resorted to. The great liability of excisions to this complication will be referred to hereafter.

In eight hundred and ninety-eight (898) instances gangrene was noted on the face of the stump. In a few of these cases the complication was caused by strangulation of the stump by tourniquet. In the following instance the gangrenous condition of the limb was ascribed to the tight application of bandages:

CASE 1205.—Captain J. Phinney, Co. K, 86th New York, aged 28 years, received a gunshot fracture of the left forearm, lower third, at Spottsylvania, May 10, 1864. When he was admitted to Seminary Hospital, Georgetown, four days afterwards, he was in a rapidly sinking condition, and the injured limb was gangrenous from the elbow down, owing to the circulation having been stopped by applying bandages too tight on the field. On May 15th the arm was amputated above the elbow joint by Surgeon H. W. Ducachet, U. S. V., who performed the operation by skin flaps and circular section of muscles. Chloroform constituted the anæsthetic. The patient began to improve within forty-eight hours after the amputation, and, with the exception of the formation of two abscesses in the stump, his improvement continued slowly afterwards. About June 30th he was able to walk about, and three weeks later he left the hospital on leave of absence. The history of the case was reported by the operator. The Adjutant General, U. S. A., reports that Captain Phinney died August 10, 1864.

But the large majority of the cases were instances of hospital gangrene caused by the crowded condition of the hospitals and the bringing together of many cases of extensive fractures and large operation wounds.

How far the frequency of the occurrence of gangrene was influenced by the season of the year cannot be ascertained from the nature of the reports; it can only be stated that in nine hundred and eighty-three (983) of the two thousand six hundred and forty-two (2,642) cases the month was not indicated; that eighty-seven (87) cases were recorded as having occurred in January, forty-eight (48) in February, forty-three (43) in March, sixty-four (64) in April, one hundred and seventy-five (175) in May, three hundred and one (301) in June, two hundred and ninety-four (294) in July, two hundred and twenty-five (225) in August, one hundred and ten (110) in September, ninety-eight (98) in October, eighty-nine (89) in November, and one hundred and twenty-five (125) in December; the highest number having been observed in June, July, August, May, and December; the lowest in March and February.

The frequency of gangrene according to the different years of the war is indicated in the following table:

TABLE CLVI.

Indicating the Years in which the Gangrene occurred.

SEAT OF INJURY.	TOTAL.	1861.	1862.	1863.	1864.	1865.	NOT STATED.
Flesh Wounds of Head, Face, and Neck	12	.....	.....	3	9	.....	.....
Fractures and Penetrating Wounds of Head, Face, and Neck	48	.....	3	13	31	.....	1
Flesh Wounds of the Trunk	75	.....	5	23	34	8	5
Fractures and Penetrating Wounds of the Trunk	141	.....	13	42	78	6	2
Flesh Wounds of the Upper Extremities	109	.....	3	27	69	6	4
Fractures of the Upper Extremities	735	2	37	144	510	32	10
Flesh Wounds of the Lower Extremities	344	.....	35	117	163	16	13
Fractures of the Lower Extremities	1,178	2	127	254	717	67	11
Aggregates	2,642	4	223	623	1,611	135	46

Only four cases of gangrene were recorded for the first eight months of the war in 1861; but it must be remembered that the medical reports for this period are very incomplete. In the following year, 1862, the number of cases of gangrene increased to two hundred and twenty-three. A few sporadic cases occurred in the hospital at Fort Hamilton, New York,

in the early part of September, among men wounded in McClellan's Peninsular Campaign in June and July, 1862. Of the three cases reported at that hospital by Surgeon B. Randall, U. S. A., one, at least, was that of a prisoner who had been carried to Richmond and had then been paroled. It was after the battles of South Mountain and Antietam, in September, 1862, that serious outbreaks of hospital gangrene occurred at the hospitals at Frederick and at West Philadelphia. The cases were carefully observed by Acting Assistant Surgeon W. W. Keen, whose report is here given:

"After the battles of South Mountain and Antietam, September 14th and 17th, 1862, an immense number of patients was accumulated in the hospitals at Frederick, Maryland. The old general hospital (No. 1), which had contained six hundred beds, was so crowded with patients that one thousand were of necessity placed in the wards, and one thousand eight hundred men were fed at its tables and slept somewhere. The hospital consisted of five old barracks of inferior character, a fine new one (built very much after the style of our wards at this place [West Philadelphia], with ventilation at the ridge-pole, either continuous or interrupted), together with a large, substantial old stone building of Revolutionary times, better ventilated by its fire-places than by its windows. To these were soon added two large new barracks, finely ventilated. Each of these buildings was entirely detached from the others, and would accommodate some eighty patients, with about six hundred and forty cubic feet of space to each in the old barracks and one thousand two hundred and fifty cubic feet in the new. Besides these, about thirty hospital tents, with eight beds in each, were pitched at various points. Here the allowance of air was only about one hundred and seventy-five cubic feet. The hospital was situated on a hill on the outskirts of the town and in a mountainous region. This, with the distribution of the buildings, procured the amplest circulation of pure fresh air.

"About the middle of October the number of cases in Barrack E, of which I had charge, was diminished from one hundred to seventy-eight. Excepting four or five, they were all severe surgical cases, a number of them being amputations, resections, or compound fractures of the thigh, and the wounds were suppurating freely. Every means to insure cleanliness and pure air was taken. Each patient had his own sponge. Oakum was largely used as a dressing, and chlorinated soda freely used on the dressings and the floor.

"Preceding October 19, 1862, three or four days of cold rainy weather set in, which occasioned the closing of the doors and windows to keep both warm and dry. On the second or third day I noticed three cases of decided hospital gangrene, all in the lower extremity; about twelve or fifteen wounds also, which had been progressing finely, stopped cicatrizing and assumed an unhealthy appearance. They were red and punctated; in some small new vessels were seen; they bled freely on removing the dressings; the parts already cicatrized became bluish red, and, in the worst looking cases, an areola of an inflammatory nature, red color, and with a hard base, was observed. The cases of decided gangrene were removed to a tent, with six beds and an allowance of space of two hundred and thirty-two cubic feet, where, under treatment, they rapidly recovered. Sixteen beds were removed and the barrack still more carefully ventilated. The weather became fine, and in two days the unhealthy sores recovered their original healthy appearance, and no more cases occurred. Two other outbreaks of the disease occurred in this barrack, one on November 8th and another early in December, running precisely a similar course. During the last an attempt was made to treat the cases in the ward without isolation, but it only ended in an utter failure, and they were again removed. Four days before it made its appearance in Barrack E the disease appeared in Barrack B, where its history was an exact counterpart of the one already related. From these two barracks, the most overcrowded and, by the way, the only ones in which erysipelas had appeared, the disease spread to all the others, in most cases, apparently, by contagion, in some clearly by infection, through the careless use of sponges, etc.; and yet, strange as it may seem, but one case appeared among the patients in the tents. They were, it is true, far lighter cases of wounds; but they were, apparently, much more exposed by the small allowance of space and by their greater proximity to the gangrene tents. When I left Frederick, December 11th, about fifty cases in all had occurred, of which some eight or ten were still under treatment and progressing favorably. Two cases had proved fatal, but by reason, it seemed, of other organic complications.

"On December 23, 1862, fifty patients were admitted to Ward No. 1, and one hundred each to Wards Nos. 2 and 3, U. S. A. General Hospital, West Philadelphia. Of these, twenty-five in Ward No. 1, eighty in Ward No. 2, and fifteen in Ward No. 3, one hundred and twenty in all, were gunshot wounds. There were at the same time two thousand three hundred and eighty-four patients in the hospital, of whom rather more than two hundred were wounded. The allowance of space in these three wards, which are contiguous, is nearly twelve hundred cubic feet to each man. But few of these new wounds were discharging freely, and scarcely any were more than flesh wounds of no great severity. 'At the time and after the admission of these patients, who were the first occupants of the wards,' says Dr. Lewis in his report for Ward 1 for January, 1863, kindly placed at my disposal by Mr. Knorr, 'the weather had been for some days unusually cold and blustering, and this portion of the hospital was so arranged as to afford no protection against draughts of air proceeding directly from the outside through open doors communicating with the passage-way leading to the ward.'

"One week after their admission, *i. e.*, December 30, 1862, I observed two cases of decided hospital gangrene, both of the thigh, in my own ward, and at the same time eight or ten of the other wounds began to look unhealthy. The cases of decided gangrene were immediately vigorously treated by nitric acid, but were not removed from the ward, and the fullest precautionary measures were taken to prevent the further progress of the disease. Since the patients could not be removed, I resolved to put the ward in as favorable a condition as possible. I ordered every other window on both sides to be lowered both day and night, and put a reliable patient in charge of the matter; I obtained a sponge for each man, directed the nurses to dress the gangrenous and unhealthy sores last of all, and to wash their hands carefully in dilute chlorinated soda afterward; used no dressing or bandage a second time, and had the soda freely used on the floor near those suffering from the disease. On the 31st no new cases appeared. On January 1st four more were observed, and from the 2d to the 18th nine more. In Ward 3 no cases whatever have appeared; in Ward 1 three cases appeared respectively on the 4th, 5th, and 8th of January. In Ward L, far removed from Wards 1, 2, and 3, one case broke out on January 17th. These, as far as I know, are all the cases that have occurred. They number nineteen in all: ten in the lower extremities, five in the upper, and four in the trunk.

"A marked contrast is thus seen to exist between the disease as seen at Frederick and at West Philadelphia. At Frederick it was notably contagious and spread widely and to every barrack; in West Philadelphia, although probably contagious, it did not invade many wounds in the same wards, nor did it spread widely to adjoining wards. There the patients were isolated, here they were retained in the wards; there all attempts to treat them successfully in the barracks failed, here it has been perfectly successful; there nitric acid was used as an escharotic, here both that and the acid nitrate of mercury. It should also be noted that both attacks followed a few days of bleak, cold, and rainy weather; that both occurred where a number of wounds were collected together; that in individual symptoms both were precisely alike, and that they improved immediately on the setting in of fine weather and under appropriate treatment; that simultaneously with the outbreak of the disease a number of wounds assumed an unhealthy appearance, which quickly disappeared under proper hygienic treatment and good weather.

"The disease, as I have observed it, is ushered in by from one to three days of unhealthy action such as already described, accompanied in some cases with marked fever, coated tongue, and prostration, but in by far the majority of cases with simply sleeplessness and general malaise. The patient complains of sharp, burning, pricking or stinging pain in the wound, sometimes so severe as to make him cry out, the suffering being intense; at others feeling rather as if the part had been 'asleep.' If the surgeon now examine the wound he will find a layer of ash-colored matter, which, as Guthrie describes it, 'covers the face of the ulcer and adhers so firmly as not to be readily removed; or, if separated, shows that it is a substance found upon the surface and constituting a part of the granulations themselves;' the edges rugged, everted, or, more commonly, undermined, or violet or livid in color; a marked areola, almost erysipelatous, surrounding the wound, an indurated base feeling very like that of a hard chancre; the discharge thin, watery, bloody, ash-colored or darker, and the wound considerably enlarged, and enlarging with aggravated symptoms, day by day, regardless of Nature's best efforts; and benevolent Art now interferes to relieve the oft-time wretched sufferer. The smarting pain and the extension of the wound (usually conjointly, but

sometimes separately) I have found to be the most distinctive characteristics of the disease. The enlargement is usually confined to the skin and superficial fascia; occasionally, however, it extends to the intermuscular cellular tissues, and, in rare instances, to the muscles themselves; arteries, large nerves, and bones resist its destructive tendency with great perseverance. The following case will illustrate the disease:

"CASE 1206.—Corporal H. H. Kuhn, Co. A, 10th Pennsylvania Reserves, aged 23, was admitted to Ward No. 2, West Philadelphia Hospital, December 23, 1862. He had been wounded ten days before at Fredericksburg, by a ball which had passed through the right thigh postero-anteriorly and inflicted a superficial wound, the openings being about two and a half inches apart. The wounds looked well. Ordered cold-water dressings. December 30th: The wound has done well up to this date. Now, however, it is surrounded by an inflammatory areola, but without any hard base, is preternaturally hot, is not enlarged, and no stinging pain is felt. Sleeplessness is the only constitutional symptom observed; ordered flaxseed poultice and morphia sulphate, grain ¼. January 1, 1863: Wound looks worse; edges bluish and livid, undermined and thickened; the base surrounding the wound hard, the areola marked both in color and size; the pain sticking or pricking, and quite severe; the surface ashy gray and punctated; it bleeds freely on removing the dressings; the two openings are coalescing, and the intervening sound flesh is unhealthy and partially destroyed. I opened it thoroughly, cut away the intervening unhealthy flesh and applied strong nitric acid to the entire surface, the patient being under ether; ordered flaxseed and laudanum poultice covered with oiled silk, and morphia sulphate, grain ¼. January 5th: The heavy slough from the cicatrization has partly cleared off, but the surface is still looking unhealthy and the pain still exists. I discontinued the acid wash and again cauterized by the nitric acid, and ordered poultice as before. The sloughing surface being large, some six inches long, I ordered 20 drops tincture of iron three times a day; still no constitutional symptoms are seen. January 9th: The slough is all gone, and fine healthy granulations are found covered with thick yellow pus; ordered the acid wash to be reapplied. January 11th: Again slightly unhealthy; ordered acid wash continued, adding five drops of nitric acid to the ounce. He now did finely, and the acid wash was gradually diluted and then simple cerate substituted until January 23d. Two or three days of stormy weather having occurred, the wound again looks unhealthy. The cicatrix is invaded at one point and looks bluish, and the discharge is less in amount and rather unhealthy in character. There is, however, no pain nor ashy surface; no areola, and no extension other than that noticed. Ordered tin foil to be applied. January 25th: The wound is vastly improved, so that I ordered the foil discontinued. January 30th: Left on thirty days furlough, doing finely.

"The question has almost uniformly been raised by authors, whether the disease is constitutional or local. Without quoting particular authorities, suffice it to say that rather the larger number regard it as a local disease, 'sometimes,' in the language of Guthrie, 'preceded by and accompanied with constitutional symptoms.' But the concurrent constitutional symptoms are no proof of a similar character in the disease, for the removal of a benign tumor, an amputation, or a gunshot wound is followed by the same. No one as yet has ever seen the disease *originate* constitutionally, but *always* locally. Wounds may become gangrenous; but hospital gangrene never gives rise to ulcers. Even where the constitutional symptoms are present, as I have seen the disease, they have been very slight, and rarely exceeded anorexia, sleeplessness, and a slight irritative fever. Of the fifty cases in Frederick I have statistics of twenty-five. In these the constitutional symptoms preceded the disease in but five cases, accompanied it in four, leaving sixteen unaffected constitutionally. Of the nineteen cases here seen there were two in which they preceded and four in which they accompanied the disease, leaving thirteen with no constitutional disturbance. The following is a case in which the constitutional symptoms were first manifested and then the local:

"CASE 1207.—Private William P. Trump, Co. D, 8th Pennsylvania Reserves, miner, aged 22, was admitted to Ward No. 2, West Philadelphia Hospital, December 23, 1862, having been wounded on the 13th at Fredericksburg. The ball grazed slightly the right shoulder, and the wound did finely under cold-water dressings. January 2d: An active fever has set in, with loss of appetite, coated tongue, and costiveness; ordered three compound cathartic pills, and tartar emetic one-eighth of a grain three times a day. January 6th: The constitutional disturbance is about the same, but local trouble has manifested itself. The usual symptoms of hospital gangrene have become developed, the wound is enlarging, and the pain is so great as to deprive him of all rest and to cause him to disturb the whole ward with his outcries. I cauterized the wound freely with nitric acid and ordered a poultice with morphia sulph. gr. one-quarter h. s. The pain ceased from that moment; he slept well; in three days the slough separated. I applied the acid wash, and he soon recovered sufficiently to desert."

"The offensive odor I have observed but in four cases, two at Frederick and two here. In cases so severe as those observed by Macleod and others, in which death occurred in sixteen hours, it was, no doubt, one of the most marked and disgusting symptoms. The case in Ward L, bed 7, was so offensive that its odor could readily be observed in the corridor, and one of those in Ward 1 was no less so. The experience of Dr. Lewis in Ward 1, as detailed in his cases, gives the most marked efficiency to the permanganate of potash in ten grains to the ounce as a deodorant. It controlled the odor when charcoal and fomenting poultices of porter and corn meal seemed to have not the least effect. It deserves further trial.

"The circular form, also alluded to by other writers, is by no means so frequent in these lighter cases; nor have I yet seen a case of secondary hæmorrhage, although I have seen the anterior tibial and the femoral itself pulsating at the base of such gangrenous sores, and in one case at Frederick, of ligation of the external iliac, the disease being communicated by a sponge, attacked the wound; and yet the artery resisted both the disease and the remedy. Should such a misfortune occur, I should unhesitatingly ligate higher up, and with the greatest precaution against infection. I should, if disease attacked the new wound, apply the escharotic immediately. But it will not

always attack every sore, and this is a serious argument in favor of its local character. I have often seen it attack a wound of entrance or of exit, and leave the other free; I have seen it attack an abrasion over the head of the fibula and leave untouched a compound fracture of the same thigh; attack an ulcer on a leg, and pass by the granulating stump, three inches lower down. I have yet to learn of a single case occurring among patients in the field—a fact fully corroborated by other surgeons who have had greater opportunities in the field than myself, and which I can only explain by the reason that the patients are usually placed in houses, or on the field itself, where free ventilation is attained, and are speedily removed into hospitals.

"As to the treatment it has been pretty fully illustrated in the cases cited. As soon as the disease is recognized I have applied either nitric acid or the acid nitrate of mercury. The former, alone, was used at Frederick; but here I have used the acid nitrate of mercury in six cases, and with the most favorable results. I prefer it, now, to the nitric acid, since it causes less pain—indeed, often it saves time vastly by requiring no anæsthetic to be used; the pain continues for a shorter time, the slough appears to be more thoroughly destroyed and disintegrated, and it separates in from twelve to thirty-six hours sooner than that from the acid. I have not yet met with a case of ptyalism from its use. The relief obtained from the severe stinging pain is often almost instantaneous, and if the disease has been thoroughly checked it does not recur. Should I have any other cases, I should also desire to make trial of a forty-grain solution of corrosive sublimate to an ounce of glycerine. But whatever escharotic be used, I cannot insist too strongly upon the necessity of its thorough application. The disease, especially in the milder form noticed here, can be eradicated by this, and by this only. It must be unsparingly applied to every spot and surface involved. Stumps must be laid bare and apparently ruined; sinuses must be fully exposed, and the disease relentlessly pursued to its furthest refuge. The timid hand, according to De Quincey the opprobrium of our profession, will not do here. The work must be thorough and complete and the remedy applied everywhere—not only to the surfaces diseased, but also to those laid bare by the knife, and even somewhat to the sound parts beyond, or the disease will spread inevitably, and kindness well meant will be really unintentional cruelty. I generally used, as a means of application, a stick rather than a mop, since, if sharp pointed, it penetrates to places which will remain untouched if a mop is used. I have then usually applied a flaxseed poultice with one drachm to a half-ounce of laudanum till the slough has separated. Poultices of meal and yeast or porter are also good. Then, if any unhealthy spots were still seen, and especially if the stinging pain had not subsided, I again made use of the escharotic, followed by a poultice. As soon as a healthy surface is obtained I began with a stimulating lotion such as the 'acid wash' already alluded to, varying its strength to the necessities of the case. Under this they have usually made a rapid recovery. In five cases I have used tin-foil applied directly to the wound, surrounded with charpie, for purposes of cleanliness, and have found it a most excellent remedy where wounds have refused to respond to other stimulants.

"I have scarcely ever used the escharotic unless the two principal symptoms, viz, the peculiar pain and the enlargement of the wound, were both present, along with the unhealthy condition of the sore. On inspection I have often been tempted in several cases to apply the acid; but finding the one or the other absent I have refrained and applied vigorous stimulation, as, *e. g.*, the 'acid wash,' sometimes further fortified by some little nitric acid, and I have been gratified to find a successful result. Tin-foil itself will sometimes alone change their character vastly for the better.

"The constitutional treatment is, I take it, of far less importance than the local, just as the constitutional symptoms are less grave than the local. Frequently they will subside entirely after the vigorous local treatment advocated. The fever will abate, the patient will sleep well, the tongue clean, the bowels relax, and he will tell you the next morning that he has eaten an excellent breakfast and 'feels first rate.' If fever sets in, I treat it as usual in any irritative fever; if the appetite and strength fail, by tonics and stimulant's and good diet. The tincture of iron, quinine, milk punch, and beef tea are the most valuable auxiliaries in such cases.

"'Hospital gangrene, the typhus of wounds,' is, in its most marked form, a fearful and unwelcome guest in any hospital, most of all in a military hospital. It claims many victims in its fierce attacks, and often puts to naught all the resources of the most skilful surgeon. But in its milder forms, such as I have seen it, and such as I have attempted to describe, the means already indicated will, I feel confident, arrest its progress and baffle its worst endeavors."

The next appearance of hospital gangrene, more serious in its character than that observed at Frederick and West Philadelphia, was at Annapolis. It appears from the report of Surgeon J. H. Brinton, U. S. V., who had been sent there to "inquire into the origin of the affection and the means which had been adopted for its treatment and for checking its progress," that on January 11, 1863, one hundred and fifty-three (153) patients were brought to Annapolis from Richmond. Very many of these men were wounded, and all had been closely confined in the prisons and prison hospitals of that city. Of these one hundred and fifty-three men, four had hospital gangrene at the time of admission and thirty-one contracted the disease within a short time. On January 29th four hundred and twenty-one additional patients were admitted from the same place and under the same circumstances; of these, gangrene existed in fourteen at the time of their admission. By February 7th the number of affected patients amounted to sixty. All cases in which the process of destruction was advancing, or in which reparation and cicatrization had not fairly set in, were collected in special wards isolated from all other buildings, and special bedding, blankets, utensils, sponges, surgical dressings, and instruments were provided for them. In this manner the disease remained almost entirely confined to the paroled prisoners. All agreed that the origin of their sores must be referred to their confinement in the Libby Prison at Richmond and the adjacent hospitals. In the prison they were much crowded, and the majority were unprovided with beds or cots, sleeping on straw which was foul and affected with vermin. Their diet, although sufficient, was of poor quality. In the hospital they received better care and every medical attention possible under the circumstances. In both prison and hospital gangrene was prevalent; many cases were said to have died, and others were stated to be in such condition from their sores as to forbid removal. The paroled prisoners who had been taken on western battle-fields referred the development of their gangrenous ulcers to tedious and painful transportation from the West to Richmond. The cars used were closely boxed; the food on the road was deficient and miserable; many of them had been altogether deprived of food for two or three days.

The treatment adopted in the Annapolis Hospital seems to have been judicious and successful. It consisted chiefly in the limitation of the ulcerative process by the application of fuming nitric acid to the edges of the sore, to its surface, and especially to the healthy integument beyond the line of diseased action. In some cases nitrate of silver had been successfully applied. The cleansing means employed during the separation of the slough were chiefly Labarraque's solution, creasote and vinegar washes, yeast, cinchona, and charcoal poultices, etc. The patient's constitution at the same time had been supported by the internal administration of muriate tincture of iron and quinine, and by the free use of stimulants, malt liquor, beef tea, and a general nutritious diet.

A few weeks after the appearance of the disease at Annapolis, Assistant Surgeon J. J. Woodward, United States Army, was sent there for the purpose of examining into the microscopical appearances of hospital gangrene. His observations are embodied in the following report:

"Arriving at Annapolis I visited the patients affected with hospital gangrene on the morning of February 18, 1863. I found that the progress of the disease was not yet arrested, and that one or two new cases were occurring almost daily. No one had, however, suffered from it except returned prisoners from Richmond, and the affection was proving much less fatal than European experience would cause us to anticipate. The patients were isolated from the rest of the hospital, in separate buildings. The number of cases in which the characteristic appearances of the earlier

stages of the disease could be observed was only three or four, and about the same number presented vast sloughing excavations, which were still enlarging in spite of treatment. In all the other cases granulating surfaces of various sizes, and in various stages of the reparative process, indicated the former extent of the disease. As the description, history, and treatment of these cases has been made the subject of special observations which will be duly reported to the department by Surgeon J. H. Brinton, U. S. V., I shall limit myself as much as possible in this report to pathologico-histological considerations.

"In its destructive progress hospital gangrene, as observed by me in these cases, appears to follow at least two diverse modes of extension, which, however, are frequently combined in different portions of the same excavation.

"I. On the one hand the tissues immediately adjacent to the slough, which have been slightly reddened without being increased in thickness, become greenish-brown, or black; the slough steadily progressing in this manner into the sound tissues, from which it is not separated so long as it continues to extend by any pus-producing or ulcerative action or any true line of demarcation.

"II. On the other hand the tissues about to be invaded become not only reddened, but hard and swollen, elevating the edges considerably, and causing, therefore, the cavity to appear deeper than it really is. This thickened mass breaks down rapidly into a fetid yellowish ichor and is thus quickly eroded, but in such a manner that the subcutaneous connective tissue is more speedily destroyed than the skin which overhangs, therefore, the jagged, irregular underminings of the morbid process. The sloughs in this case are ash-colored, yellowish, or greenish-yellow, occasionally brownish or blackish, in which latter case it will generally be found that the dark color is due to the putrid mass drying into a species of scab.

"In both these varieties the slough attacks chiefly the skin and subcutaneous connective tissue and adipose layer. The second variety, however, more frequently than the first, may penetrate beneath the deep fascia of the part, still affecting especially the connective tissue septa, dissecting thus profoundly between the muscles and tendons, which resist longer the destructive process, and retain often their general form and appearance even after they have been completely undermined and separated, except at their extremities, from their normal connections.

"In the first variety an examination of the slough as close as possible to the living tissues showed nothing but the normal form elements of the affected part in various stages of putrefactive decomposition. None of the lymph or pus-forms which usually result from inflammatory action could be observed. The small vessels and capillaries of the living tissues near the slough were gorged with blood, which, in the vessels immediately adjacent to the dead parts, was completely stagnant. In proceeding in the investigation of the sloughs of this character from the living tissues through the slough to the central cavity exposed by the disease, the elementary forms were found to be more and more completely obscured by the putrefactive changes until a granular opaque mass remained in which no form elements could be observed, except perhaps a few yellow elastic fibres which had resisted decomposition. Associated with these changes was a tendency to break down into a fetid, diffluent semi-liquid, and thus to leave a cavity which in this class of cases was usually bounded below by the superficial surface of the muscles of the part. In these cases it was generally observed that while the disease continued to spread peripherally, a line of demarcation was formed by a true ulcerative action with pus-formation between the superficial slough and the subjacent muscles, the pus being formed in at least some of the cases at the expense of the muscular tissue, as will be seen in the sequel.

"In the second variety an examination of the thickened and hardened edges into which the eroding process was extending showed the tissues to be transformed into a mass of cell forms, of which the most numerous were spherical granular cells, quite identical in individual aspect to ordinary pus corpuscles, but embedded in a granular mass, and thus constituting what has been variously called croupous fibrine, croupous lymph, and corpuscular lymph. This is the condition described by Rokitansky as the 'death of textures replete with fibrino-croupous exudates,' to which category he refers hospital gangrene. Embedded in the same mass can also be seen occasionally connective tissue cells in various stages of enlargement and multiplication by division. By the liquefaction of the granular mass in which these elements are embedded they float out free, forming a scanty ichorous pus. The process, therefore, in this variety consists of two stages: In

the first there is an extremely rapid cell multiplication, resulting in the formation of the innumerable cells of croupous lymph with which the tissues are crammed; in the second the death of the infarcted tissues occurs either *gradatim* as an eroding ulcer or in mass as a bulky slough.

"In cases of either variety in which a favorable termination is attained after the sloughs are thrown off, granulations sprout from the bottom and sides of the cavity and gradually fill it up. In one or two cases in which this process had advanced to commencing cicatrization nothing was observed different from what may be seen in the healing of ordinary ulcers of considerable size. In many favorable cases, however, granulations sprout from the exposed muscles at the bottom of the excavation even before the extension of the sloughing at the margin is arrested. I found in these cases, as well as in the ulcerative process previously mentioned, by which the black sloughs of the first variety are separated from the subjacent muscles, a good opportunity to study the process of pus-formation in the muscular tissue. The observations made here confirm precisely, as do many others made by me heretofore, the opinion that the muscular fibre, when involved in the inflammatory process, contributes its share to the formation of the products of inflammation. The form elements involved especially are the so-called nuclei of the sarcolemma, concerning which there is a difference of opinion as to whether they are to be regarded as an anatomical portion of the muscular fibre or as belonging to delicate connective tissue cells wound spirally around it. These, whatever their nature, enlarge, elongate, multiply by division, and produce broods which encroach on the proper substance of the fibre. The transverse striæ become pale, indistinct, and at length are replaced by a granular appearance. Finally the whole substance of the fibre is occupied by spherical granular cells, the destiny of which may be on the one hand to develop into granulations, or, on the other, to be set free as pus by the liquefaction of the matrix in which they are embedded.

"With regard to the constitutional conditions present in these cases of hospital gangrene the patients were pale, the countenance anxious, the pulse frequent, small, feeble, the bowels sometimes affected with diarrhœa but in other cases constipated. The appearance of the patients in some cases indicated the presence of a scorbutic taint. In other cases the yellow complexion and the enlarged spleen indicated constitutional disturbances due to malarial poisoning. In all it was observed that a needle inserted into the finger to obtain a drop of blood for examination required to be carried deeper than usual to obtain it. The blood thus obtained presented in every case a noticeable increase in the proportional number of white blood corpuscles, which were also, as a rule, larger than normal ($\frac{1}{2800}$ to $\frac{1}{2500}$ of an inch in diameter). This condition was developed in some cases much more than in others, but in none attained to an exquisite degree. The red blood corpuscles were scanty, pale, and showed less tendency than in healthy blood to aggregate into nummular rolls.

"If now, in appreciating the foregoing observations, an attempt be made to recognize the etiology of the affection, we shall seek for the efficient causes in the exposures, the privation, the want and depressing agencies to which these men had been exposed in the crowded prison hospitals of Richmond. It was there that the affection originated, and although new cases still from time to time occur in Annapolis, it will be borne in mind that, as previously stated, these cases occur only among the wounded of the returned Richmond prisoners. The escape of these unfortunates to the open wards, the generous treatment and good diet of the United States General Hospital, will account for the small mortality that has occurred.

"In conclusion, an allusion may be made to the idea that the peculiar characteristics of this disease are due to the local presence of microscopical fungi. This idea is not borne out by facts. Accurate examination with a high magnifying power of cases in every stage, both where nothing but an ordinary water dressing as well as in cases in which various forms of antiseptic and caustic washes had been employed, utterly failed to demonstrate any cryptogamic organisms except the ordinary bacteria which are to be observed in every decomposing animal substance."

While, at Annapolis, the cases of hospital gangrene had been produced by infection, the disease at Nashville, where it appeared a month or two later, in April, 1863, was undoubtedly of an indigenous origin. Thirty-eight cases occurred at hospital No. 8 within a few days, and Surgeon M. Goldsmith, U. S. V., who had been sent there to look into the origin and progress of the disease, found that—

"I. All of the cases occurred in Ward No. 1. II. All the cases occurred in the row of beds

next the windows opening upon an alley. III. All the cases occurred prior to the 24th of April, or during the time when the external atmosphere was colder than that of occupied houses, enclosed cellars, or underground drains. IV. The cellar under the hospital had passing under and opening into it by several apertures the common sewer of that part of the city. V. The soil pipes from the privies of the several wards traversed this cellar and emptied without a trap into the common sewer. VI. This soil pipe was made of tin and leaked badly. VII. In wet weather the cellar bottom was overflowed by the contents of the soil pipes and sewer. VIII. This cellar had but two openings, one in the front of the building and one on the alley. IX. The alley was long, narrow, and high (five stories). X. The area of the adjacent building received the drainings of the garbage of the kitchen, and this area formed a part of the alley. XI. Ward No. 1 derived its ventilation almost entirely from windows opening on the alley. On the opposite side there was but one opening, a door, leading to a hall which had no window. On the end next the street there were but three windows. XII. The prevailing winds during cold weather sweep the street on the front of the building, leaving the atmosphere in the alley almost still. XIII. The emanations from the area of the adjoining building, as well as those from the cellar, were most offensive at all times, and were disgustingly perceptible in the evening when the external atmosphere began to grow cool. XIV. No cases of hospital gangrene occurred after the weather grew so warm that the outer air was warmer than the air in the cellar and sewer (after April 24th). XV. The building on the opposite side of the street (the alley running through only one square) prevented any wind from sweeping it below the second story.

"In the early part of the season one patient was brought into the ward with hospital gangrene. In a few hours six other cases were developed in wounded men laying adjacent to him. The disease did not spread, and with the termination of these cases disappeared for a season. When it broke out again it attacked those who came into the ward without any appearance of a gangrenous condition in their wounds at the time of their admission. It will appear from the fact related that the miasm generated by putrefying animal matters in the cellar, and perhaps in the area, are given off at all seasons, and that just during that season when, from the relations of temperature, the atmosphere of the cellar would ascend in the alley and the currents would enter the wards most constantly—*i. e.*, when it was necessary to heat the ward with stoves, the cases of gangrene occurred; and that they occurred in just that locality in which the gases would impinge upon the patients in most concentration; and that when the miasm of the cellar would flow downward, *i. e.*, when the external air was warmer than the air of the cellar, and when from the extinction of fires no air was drawn in at the windows, the disease ceased.

"The testimony of the surgeon having the ward and cases in charge is all the more valuable that he did not anticipate or interpret the facts. He noticed, without peculiar interest, the occurrence, and, as he expressed himself to me, supposed that by some singular accident the patients having the 'lowest vitality' were placed in that row of beds; and he marveled greatly that the cases should occur when the ventilation was best, because the windows in the alley were the only available outlets for air in the whole ward, and were opened fully and diligently four times a day in even the coldest weather, and some part of the windows were kept open all the while.

"I think that the records of surgery do not afford a more unique or striking example of one of the methods of the production of hospital gangrene, or afford a more pertinent commentary upon the use of buildings constructed in utter disregard of all hygienic rules. It is due to the Medical Director at Nashville to state that he had closed this hospital, and reopened it only when the crowd of patients coming from the front was so great that they could not be accommodated otherwise, either in Nashville or at Louisville, and also to state that the attention of the Quartermaster's Department had been called to the condition of the building.

"I found some cases of hospital gangrene in process at the field hospital at Murfreesboro', Tenn. The wounds in the same and adjoining tents had an unhealthy look, and some were attended with profuse and unhealthy suppuration. A few of the cases were already laboring under the ichorous infection (pyæmia). The general police and attention to sanitary regulations were good except in one particular—a particular to which, I fear, but little attention is commonly paid—I refer to the privies. The tents are arranged on two sides of the square, end to end, along parallel streets laid out in squares, each row, I believe, being regarded as a ward. The privies are placed along a middle line bisecting a square, and distant, as near as my memory serves, about twenty or

thirty yards from the tents. These privies are open sheds placed over shallow sinks, nowhere deeper than an ordinary field latrine. The flooring is so loose that the whole arrangement is the equivalent of three square, large field latrines, with only this difference, that in the field they can be policed by throwing in earth, while, in the present case, they were broad and shallow pits filled almost to the surface with a pestilent semi-fluid mass, the excrement of men affected with typhus, dysentery, diarrhœa, etc., etc., and incapable of the ordinary treatment of field latrines. At the time of my visit the streets surrounding the square were filled with the odor of these sinks—an odor such as is only to be perceived in the neighborhood of such collections—a nauseous odor, not mere ammoniacal odors, but a sickening phosphorescent odor. For some days prior to the appearance of the hospital gangrene the atmosphere had been remarkably still and damp and the weather warm and cloudy; what little wind there was had been from the east. The tents holding the wounded were at the westward of the privies. I state these facts not for the purpose of intruding upon the province of the medical inspectors, or as a text for any comment other than that in them I can see clearly the operation of causes proverbially potent in giving rise to hospital gangrene, erysipelas, and congeners.

"In Nashville I found a few sporadic cases of hospital gangrene, some of which had been treated with bromine unsuccessfully. In examining the methods of applying the remedy I found that the applications had not been properly made. I requested permission to show the surgeons my methods on one of the cases. I dressed the first case in the presence of a number of medical officers. This method was applied to all the other cases in the city on the same afternoon, and I had the satisfaction of seeing that every one of them yielded to a single application of bromine, and in less than forty-eight hours were granulating throughout the whole extent of the diseased surface. The affair of these cases, I am informed, has settled all doubts lingering in the minds of some of the surgeons on duty at that place in regard to the efficacy of the bromine treatment of hospital gangrene."

As a prophylactic against this disease, Medical Director M. Goldsmith, U. S. V., ordered the following compound solution: "Bromine, one Troy ounce; bromide of potassium, one hundred and sixty grains; distilled water, enough to make four fluid ounces of the entire mixture. At the same time printed directions for its use were issued as follows:

"1. *For Fumigation:*—Place vessels containing *one ounce* of the solution at different points of the ward, and in number sufficient to secure in the latter the constant presence of the odor of bromine. It should be borne in mind that if the vapor of bromine comes in contact with the vapor of water, hydro-bromic acid is formed; therefore, when there is much of the vapor of water disengaged in the apartment the quantity of the vapor of bromine must be correspondingly increased.

"2. *Topical application of the vapor:*—A piece of *dry* lint is to be placed over the diseased part; over this is to be placed another piece of lint *moistened with the solution of bromine;* over this, a *third* piece *spread with simple cerate;* the whole to be covered with oiled silk and bandage, so arranged as to retain the vapor in contact with the diseased surface as long as possible. The solution is to be renewed as often as it becomes exhausted by evaporation.

"3. *The solution, in substance, as a direct application in Hospital Gangrene, Diphtheria, Gangrene of the Tongue,* and other diseases of this nature:—The parts are first to be dried by the application of charpie; then the sloughs, if thick, should be trimmed out with forceps and scissors as much as possible, for the thinner the slough the more effective is the remedy. The parts having again been dried, the solution is applied by means of a mop, or a pointed stick of wood, in quantity sufficient to saturate the sloughs. If the sloughs undermine the skin, or dip down into intermuscular spaces, the solution must be made to follow, with the pointed stick or by means of a glass syringe with a long nozzle. If the application has been effectual, all odor from the diseased surface ceases and the sloughs become somewhat hardened. The remedy should be reapplied every second hour as long as any odor of putrefaction is present, or as long as the sloughs appear to be diffluent. It is not always necessary, especially when the sloughs are diffluent and thin, to use the solution in its full strength; it may be weakened by the addition of water as the disease subsides.

"The points to be especially attended to, in the use of the solution of bromine, are two: 1. The solution should be applied in strength and frequency sufficient for the impregnation of *the whole of the sloughs.* 2. To secure this end, the application *should be made by the surgeon himself,*

and never be trusted to a nurse. If the sloughs are thick and cannot well be trimmed, the bromine may be introduced into the thickness of the slough by means of a hypodermic syringe. After the topical application of the solution the parts, when so situated as to render it practicable, should be subjected to the influence of the vapor. (See par. 1.) Surgeons will do well to bear in mind that bromine is a new remedy for the purposes indicated above. The directions for its use, given here, are those followed in the military hospitals of this city; it may be found advisable to modify them as experience with the remedy accumulates. It is, therefore, earnestly recommended that the subject be studied diligently, that the effects of the remedy be carefully watched, and that the application be varied as new facts are developed in its use."

The action and influence of bromine thus employed will be best understood from the reports made to Surgeon Goldsmith by several surgeons in charge of hospitals under his direction in which the disease occurred. Surgeon B. Woodward, in charge of the Park Barracks Hospital, Louisville, Kentucky, reported:

"In hospital gangrene the most remarkable effects of the use of bromine have been seen. At hospital No. 7 there is one case of gunshot wound of the foot in which the gangrene included the whole upper part of the foot from the toes to the tarsus. The integuments and muscles had all sloughed away, leaving the extensor tendons bare and isolated. The local use of the bromine had arrested the slough, and the line of demarcation was well marked. Another was at the same hospital of wound of the leg by a piece of shell; the gastrocnemius and soleus were bared for a space of eight inches by three inches; after the direct application of bromine the line was well marked, and the wound took on healthy action. In a third case at the same hospital the tibia was bared and denuded of periosteum, but the same good results were had from the use of bromine. At hospital No. 3 I was shown two cases of gangrene; in one the slough had destroyed not only the muscles of the right arm, but the humeral artery had sloughed and had been ligated. Another and perhaps the worst case at the same hospital, where the slough had carried away integument, obliquus externus and obliquus internus, so that for a space of eight by five inches there was nothing left but the tendons of the obliquus internus and the peritoneum, the sloughing had been arrested, and the whole wound was covered with healthy granulations. In all these cases the peculiar fetor of gangrene had disappeared. All these cases were mixed in with sick and badly wounded men, and yet there had not been an instance in which others had taken the disease. All of these cases were gangrenous when they were brought from the front to this city, and I cannot find an instance in which it has originated here. This, as Dr. Goldsmith, in charge of hospital No. 7, said, 'can only be attributed to the prophylactic power of the vapor of bromine in the wards,' and, to use his own words, 'we are doing with the greatest impunity what, a year ago, we should not have dared to do, viz, putting these cases in the wards with other wounded men.'"

Surgeon Thomas H. Mercer, U. S. V., records in detail in the following case the manner in which bromine was employed at hospital No. 13, Louisville:

"CASE 1208.—Corporal Jesse Havens, Co. F, 69th Regiment Ohio Volunteers, was admitted to hospital No. 13, Louisville, Kentucky, January 14, 1863, having been wounded at the battle of Murfreesboro', December 31, 1862, by a conical ball in the anterior tibial region, lower third of leg; flesh wound. The wound did not bleed at all at the time of the injury, but appeared to remain from that time until January 13th in about the same condition, with no disposition to granulate or heal. At that time, or very soon after, the edges of the wound and flesh in the vicinity began to assume a purplish hue and unhealthy look. Water dressings used up to February 1st; wound and surroundings growing worse daily. The wound then commenced sloughing and extending, with a dark gray and blackish appearance. At this stage of the disease was commenced the antiseptic treatment, the yeast poultice with cinchona and charcoal; after a few days nitric acid, diluted one-half, applied directly to the wounded surface and gangrenous surroundings, with some slight improvement. This was continued for several days. Bromine was then commenced, twenty drops to one ounce of alcohol, as a substitute for the acid, with the cinchona and yeast poultice applied immediately after the use of the bromine. Up to this time, February 20th, Acting Assistant Surgeon John Logan had the care of the case; the treatment constitutionally was sustaining. The gangrenous sloughs were becoming detached and the surface of the wound was looking well, but very pale after removal of the sloughs. February 21st: Wound cleaning; some soft, pultaceous sloughs remaining on the inferior third of the ulcerated surface. This wound, not exceeding a twenty-five-cent piece in size when the patient was admitted, now extends some seven inches inferiorly and superiorly, and about five inches—two and a half on either side of the leg; applied the bromine twice a day over the surface of the wound and around the edges for an inch or more. Ale, sulph. ferri gr. 1 every four hours; diet generous. February 22d: Soft pultaceous masses of slough removed with forceps and scissors. Bromine, ale, and iron continued. Appetite improving. Yeast and cinchona poultice as usual. February 23d: Pearly edge developing around the ulcer; pulse 92; general surface of the wound looking well, and some disposition to granulation. Tongue slightly furred, appetite pretty good; patient more cheerful. Ale, iron, etc., continued. February 24th: Tongue improved, pulse 90; improvement in general appearance. Skin clear, mind tranquil, granulations appearing over the entire surface of the wound, except a gangrenous spot about the size of a dime on the inner surface of the tibia, about the central portion of the wound, involving the periosteum. Appetite improving. Bromine, ten drops to the ounce of alcohol, proves as much as he can bear. Continue treatment as before. Generous diet. February 25th: Tongue clean, pulse 90, appetite good;

gangrenous spot lessening; granulations increasing; surface ulceration improving in color; treatment the same as before. February 26th: Tongue clean, pulse 96, appetite good; gangrenous spot lessening in width, slightly increasing in length; wound still improving and filling up with fine healthy granulations. February 27th: Feels better; tongue clean, pulse 88, appetite good; gangrenous spot about the same; granulations improving all the time; feels cheerful and hopeful. February 28th: Pulse 84, tongue slightly furred; application of bromine quite painful for an hour or so after its use. March 1st: Pulse 84, tongue cleaner, wound looking well; bowels in good order throughout since February 20th, previous to which time he had frequently suffered from sharp attacks of diarrhœa. March 2d: Tongue clean, pulse 86, wound filling with fine healthy granulations; bowels not so easy; some griping pains in epigastrium; countenance, however, cheerful. Gangrenous spot entirely devoid of the soft pultaceous mass, leaving the periosteum exposed about the size of a five-cent piece and black as ink. Appetite not so good; ordered wine to substitute the ale; diet generous. March 3d: Pulse 88, tongue slightly furred, wound improving, bowels better; cheerful and hopeful; appetite good; treatment continued. March 4th: Pulse 86, wound about the same; tongue clean, bowels in good condition; gangrenous spot still the same. Diet generous and full. March 5th: Pulse 88, tongue slightly furred, appetite good, wound gradually and steadily improving. Application of the bandage to the foot up to the edge of the wound to prevent burrowing. March 6th: Pulse 88. Complains of some pains in the right side of the chest on taking a long breath. Wound still improving, appetite good. Ordered mustard sinapism to chest, and Dover's powder, grains 15, at night. March 7th: Pulse 90, tongue clean; pain in chest relieved; appetite good as usual; wound still improving. March 8th: Pulse 108, tongue coated; pain returned to the right side; not as well to-day; spirits depressed, appetite still good, bowels regular. Mustard sinapism to chest; pulv. Doveri, grains 25, in four powders, one every three hours; same treatment of wound. March 9th: Pulse 96, tongue about the same; general condition much improved; pain in side relieved, appetite good, and in good spirits; wound healing. March 10th: Pulse 88, tongue cleaning, wound painful, but improving in appearance; appetite good. Treatment the same. March 11th: Pulse 96; condition about the same as yesterday. Treatment and diet continued; wound healing rapidly and prettily. Bromine has acted like a charm, and still possesses a biting character when applied, from which he suffers for an hour or so after its use."

Surgeon Goldsmith gives a statistical summary of three hundred and thirty-four (334) well authenticated cases of hospital gangrene treated at the military hospitals at Louisville, Kentucky, Nashville and Murfreesboro', Tennessee, and New Albany, Indiana, and remarks that the testimony of these cases will establish the value of bromine in hospital gangrene sufficiently at least for the purpose of challenging investigation.

TABLE CLVII.

Summary of Three Hundred and Thirty-four Cases of Hospital Gangrene, giving Treatment and Results.

TREATMENT.	TOTAL CASES.	RECOVERED.	DIED.	AMPUTATIONS.	AVERAGE DURATION OF TREATMENT.	PERCENTAGE OF MORTALITY.
Treated with Bromine in different ways	152	148	4	.....	5 days 14 hours	2.6

Surgeon J. H. Brinton, U. S. V., who had examined the outbreak of hospital gangrene at Annapolis, reports of the cases at Nashville that—

"Although of an analogous form the disease did not appear to me to be of so virulent a grade; whether this was due to the original character of the affection, or to the effect of the remedial measures employed, I am not prepared positively to decide. Nearly all the cases observed by me were in the stage of reparation, and but very few in the period of progress. The shape of the ulcers was characteristic, as was also the appearance of the gray slough, but the tendency of the sores to burrow deeply and to extend rapidly was not well marked at the time I examined the cases, some thirty in number. The treatment almost universally adopted in the Louisville hospitals is that originated and introduced by Surgeon Goldsmith, U. S. V. It consists in the direct local application of bromine, either pure or in solution, to the surface of the sloughing sore. Due care is always first taken to remove as thoroughly as possible the sloughs, so that the agent may act on the living tissues and permeate them to some extent. In cases in which the burrowing is so extensive and deep seated as to render the application of bromine difficult or incomplete, Dr. Goldsmith resorted to hypodermic injections of bromine at the circumference of the sore. The

punctures with the point of the syringe are made at intervals of from one-half to three-fourths of an inch, and one drop of the pure bromine is thrown into the tissues at each application. The mode of dressing the surfaces of the sores with the bromine was exhibited to me by Dr. Goldsmith. From my observation of the immediate effect of the reagent upon the diseased tissues, and of the condition of the sores upon which it had been previously applied, I am inclined to look upon the remedy as one of great value and well deserving of a fair and extended trial. * * I would here remark that in the Louisville hospitals but little tendency has been observed in the disease to spread from bed to bed, although isolation of the gangrenous patients has not been enforced. In my own judgment the absence of this tendency to infection tells strongly against the supposed virulence of the affection, and would ever throw doubts on its true nature—at all events in some instances. Assuming the disease, however, to be the veritable hospital gangrene, the facts connected with its origin were peculiar. The disease occurred almost always in patients who had been wounded at the battle of Murfreesboro', and who had been retained for some time in crowded hospitals previous to their transportation to Louisville. I am informed by Surgeon Thurston, U. S.V., Medical Director of the Nashville hospitals, that no one upon whom the gangrene had already appeared was ever sent from Nashville, and yet many were so infected when admitted to the Louisville hospitals. The development of this disease on the route seems to have been owing to the fact that the transportation of the wounded was effected by means of crowded and illy ventilated boats, and that the trip by the Cumberland and Ohio rivers frequently occupied several days. During this time these patients, who had already undergone much suffering, were exposed to all the influences most apt to engender this disease. In contrast with this fact it was found that as soon as the Louisville and Nashville Railroad was opened so that the wounded could be conveyed from city to city in hospital trains in one day, all importations of gangrenous sores into Louisville ceased. The development of hospital gangrene during the boat transportation is a noticeable fact, and is strikingly analogous with the same phenomena observed among our paroled wounded prisoners from Richmond received into the Annapolis general hospitals some months since."

It is well to state here that a few at least of the surgeons at Louisville and elsewhere did not entertain the favorable opinion in regard to the use of bromine in cases of hospital gangrene expressed by Drs. B. Woodward and M. Goldsmith. Acting Assistant Surgeon John E. Crowe, in charge of General Hospital No. 4, Louisville, reports in July, 1863, that it was efficacious in "very superficial wounds attacked with hospital gangrene; but when the disease attacks a large or deep-seated wound it has failed, after repeated trials, to exert any beneficial influence. Creasote is superior to it in this class of cases; yet creasote has failed in several instances." Dr. W. W. Keen considered bromine a poor agent, painful, inconvenient; the suffocating fumes preventing a close inspection of the wound. Surgeon J. E. Summers, Medical Inspector, Department of Tennessee, believed that there was a "tendency on the part of surgeons interested in the bromine treatment to regard every slough as gangrene."

In February, 1863, a number of cases of hospital gangrene occurred at the Douglas Hospital, Washington, D. C., and were observed by Assistant Surgeon William Thomson, U. S. A., who, in a special report to the Surgeon General, gives the following interesting account of the pathology and treatment of the cases. In several instances later information has been added to the cases cited by Dr. Thomson:[1]

"The victims of this disease were wounded at Fredericksburg, December 13, 1862. For several weeks previous to this battle the army had been resting on the Rappahannock and had been exposed to no great hardships. It had been amply supplied with good and varied food, and the men were free from any scorbutic or other cachectic taint.

"It is well known that the fullest preparations had been made by Surgeon Letterman for that engagement. The operations were performed promptly, and the wounded probably received better care than ever before in the history of the war.

[1] The report has been published in the *American Journal Medical Sciences* for April, 1864. Vol. XLVII, p. 378.

"On the 26th of December, 1862, about two hundred wounded from the battle of Fredericksburg were received into the Douglas Hospital.

"I cannot speak of their treatment, medical, surgical, or hygienic, as at that time I was not connected with the hospital. I am, however, aware that the building in which the gangrene appeared contained fifty badly wounded and recent cases; that there was a deficiency of medical officers and dressers to insure the necessary cleanliness, and that the sanitary condition of the ward was far from perfect.

"This hospital consists of the three brick houses known as 'Minnesota Row,' and two large wooden pavilions, each divided into two wards. The ward in which this disease originated is one hundred and forty-three feet in length, twenty-three feet in breadth, and sixteen feet in height (eighteen feet at the cone and fourteen at the eaves of the roof), and contains beds for fifty patients, thus giving 1,050 cubic feet of space for each bed. There are two rows of windows, the lower of which contains two, the upper one sash each; the upper windows so constructed as to be opened by means of a cord, but when opened directing a current of cold air immediately downward upon the beds beneath.

"On the 16th of Feburary, 1863, I took charge of the hospital, and found the ward mentioned in the following condition: There was no ridge ventilation, nor was there any egress for foul air except through two large wooden shafts connected with two of the stoves, which had been placed there only a few days previously. The ward was heated by ordinary sheet-iron radiating coal stoves, and no provision had been made, until a few days before, to introduce any supply of fresh air. It contained from forty to fifty patients, all wounded, many of them very severely. The police was not unexceptionable, too little attention having been paid to the removal of offensive discharges. The medical officer in charge preferred to water as a dressing either simple cerate or mutton tallow, which had been issued to the hospital, and which had become rancid. The attendants were, from a want of strict discipline, careless and inattentive. There was a perceptible and offensive odor in the ward, which felt close and badly ventilated; and this condition of the atmosphere seemed to have a marked effect on the spirits of the men; they were all gloomy, despondent, and homesick.

"On February 17th, when making my first visit with the officer in charge of the ward, I discovered:

"CASE I.—Sergeant Otto Kosack, Co. K, 2d Maryland, who had been struck by a shell, December 13, 1862, which made it necessary to amputate his left leg at the middle. The operation was done ten minutes after the injury. He was received here on the 25th of December. The stump closed by granulation, a small portion of the tibia having been removed by exfoliation. The cicatrization had been almost complete, when, a few days previous to the 17th, the still open wound commenced to slough. He was anæmic, very pallid, haggard, and with an expression of great depression in his features; his pulse was very feeble and rapid; he had been 'feeling very badly' for several days, and complained of a burning pain in the stump. On the outer side of the tibia there was an ulcer one inch in diameter, covered with a yellowish-gray pultaceous slough, and a serous and very fetid discharge; the edges were thickened and everted, and an areola of purple livid congestion extended for half an inch from the margin, which was undermined. This sore was at once treated with pure nitric acid, applied both to the ulcer and to the areola; the ulcer was dressed with an antiseptic solution of creasote, and citrate of iron and quinine, with stimulants and nutrients, were freely given. On the 18th the sloughing had extended to the border of yesterday's livid areola, but was now more superficial, and the areola, which had likewise invaded the surrounding skin, was more florid. The ulcer was now two inches in diameter. As there was some doubt as to its specific character, the patient was not removed from the ward until the 23d, when he was transferred, with several others, to a small ward prepared in the brick building, and completely isolated from the other wounded men. The iron and quinine were found to disturb his stomach and destroy his appetite, and was replaced by a mixture of nitro-muriatic acid and tincture of opium. March 3d: The sore was now perfectly healthy and was granulating rapidly. [The patient was discharged June 15, 1864, and was a pensioner in 1882. A plaster cast of the stump is preserved in the Army Medical Museum and is numbered 6706 of the *Surgical Section*.]

"This was a mild case, treated in its incipiency with nitric acid most thoroughly. The ulceration had not extended so deeply, nor so far beneath the margin of the skin, as to make it almost impossible to reach every portion of the diseased surface. There was no scorbutis. The gums were firm and hard. The patient was very pallid, his heart feeble, and his pupils dilated. The mucous membranes were very pale, and the expression of the face haggard and anxious. He recovered rapidly with a good stump, and was seen, several months after, walking with great ease on an artificial leg.

"CASE II.—L. D. Thurston, Private, Co. A, 16th New Hampshire, aged 42 years, was struck by a fragment of shell on December 13, 1862, at Fredericksburg, which caused a severe but superficial wound of the integuments on the outer side of the left thigh. When seen, February 17, 1863, there was a wound at the middle of the thigh, on its outer aspect, three and a half inches long by two and a half wide, exposing the muscular tissue slightly, the surface of which was glazed and dry. On the 10th of February it had been found desirable to open an abscess three inches below the left greater trochanter. On the 13th this had assumed an unhealthy look, and when I saw it on the 17th the incision made by the lancet, half an inch in length, was surrounded by a border of sphacelus one inch in width, and by an areola of purple congestion, in which there seemed to have occurred a complete stasis of the circulation. There was no pus, but a discharge of very fetid dark-colored serum. There was

no swelling, ulceration, or eversion of edges of the incision, which, although mortified, remained as sharp as when first made. There was profound nervous prostration, which was indicated by his rapid, feeble, and irritable pulse; by his sallow hue; his haggard and anxious expression of countenance; his weary and helpless decubitus and great mental despondency. He was treated internally with stimulants, the most condensed and nourishing food, and citrate of iron and quinine; nitric acid was applied locally, followed by a weak solution of creasote, three drops to the ounce of water, as an antiseptic dressing. The sphacelus extended in all directions rapidly, unchecked by this treatment, from which I hoped little, since it was impossible to bring the acid into contact with the diseased tissues, although it was injected into the incision. The constitutional symptoms also became more grave. On the night of the 20th there was quite a severe hæmorrhage from the incision, oozing slowly, and very difficult to restrain, since it was caused by the erosion of vessels at a distance from the small incision. There was now a circular patch of sphacelus surrounding this small incision, three inches in diameter. On February 23d he was removed to the ward in the brick building. The original wound, hitherto unaffected, now began to be black and offensive. The sphacelus extended from these two centres at the rate of one inch daily, preceded by the above-mentioned areola of purple stasis. No treatment, local or constitutional, produced the least effect. Stimulants were given in every possible form, until the stomach refused to retain them. Pure nitric acid was freely applied to the diseased surfaces with no benefit. He fell into a typhoid condition, with muttering delirium, subsultus tendinum, etc., and finally expired February 28th. The sphacelus then extended from the trochanter major to three inches above the outer condyle, and from the median line in front to a corresponding point behind. There had never been any ulceration, but the tissues seemed to perish *en masse*. The incision made by the lancet was yet plainly seen in the centre of any extensive surface of mortification. This man was 42 years old, had had chronic diarrhœa, and was in a feeble state of health when wounded. No benefit was observed from any treatment. He took in addition to the nutrients and tonics the acid mixture with tincture of opium. [A wet preparation of the thigh, exhibiting the ravages of hospital gangrene, is *Specimen* 1001 of the *Surgical Section*, A. M. M.] * * *

"CASE V.[1]—Isadore Wick, Co. D, 1st New York Artillery, aged 32 years, had his right thigh amputated on the field, for comminuted fracture of the tibia, received December 13, 1862, at Fredericksburg, caused by a minié ball. He was admitted December 26th. I regret that I can give no account of his progress, but I learn that the flaps had been insufficient, and that the stump had been closing by tedious granulation. There had been a free discharge, and his general condition was, therefore, unfitted to withstand the depressing influence of hospital gangrene. His bed was on the same side of the ward, and in close proximity to the first case reported. The operation had been a circular one; the granulation had entirely covered the end of the bone, and there was, when seen on the 18th of February, only a narrow strip, not yet cicatrized between the margins of skin. This was now covered with a gray slough and had the characteristic fetid odor. It was dressed simply with the creasote solution, my faith in the acid treatment having been shaken by the reports of medical officers who had visited the cases at Annapolis. February 23d: The case was now considered an unequivocal one of hospital gangrene, and was removed to the ward selected for such cases. The cicatricial tissue had all yielded to the sloughing, and the subcutaneous connective tissue had been destroyed for two inches beneath the skin at the outer angle of the original incisions. No change was made in the local treatment, as the creasote was a perfect deodorant, and as good results were hoped for from its local use, as had been reported from Annapolis. The destruction was limited to the connective tissue until March 9th, when there was a margin of sphacelus half an inch wide in the true skin. The constitutional symptoms had been growing more grave. His mental despondency was most marked, his face pale and anxious, his pupils dilated, his pulse 100 per minute and feeble, and his skin very moist; a free diarrhœa had also commenced. The tonics and stimulants, having produced anorexia and nausea, were replaced by a mixture of tincture of opium and hydrochloric acid in such proportions that he took gtt. xvi of tr. opii and gtt. iv of acid. hydrochlor. every fourth hour. Beef essence and milk punch were given as freely as his stomach would tolerate them. 11th: As his general condition became less favorable the local action was changed from molecular death to sphacelus. The whole face of the stump has now a margin of black mortification of the skin, outside of which was the usual areola of purple congestion—the complete stasis of to-day becoming the sphacelus of to-morrow. The end of the femur, protected by rosy granulations, now protrudes from the black mass of sphacelus, the integument having become loosened by the destruction of the subcutaneous connective tissue and retracted. The presence of this mass of putrefaction seems to add to the nervous prostration, if indeed the absorption of such peccant material is not its sole cause. Pure nitric acid had been applied several times, but it had been found impossible to convey it into the depths of the ulcer. 21st: No change except for the worse had occurred. Stimulating poultices of cinchona, ginger, and flaxseed had been used locally, but with no benefit. Antiseptics, such as the solutions of chloride of soda, creasote, and permanganate of potash, were necessary to purify the ward and render it endurable for his attendants. Nutrients and stimulants had been pushed to the last extent, and opium had been largely given for its supposed specific effect in the disease as well as to allay suffering. The symptoms had been typhoid for several days; emaciation had gone on rapidly; there had been subsultus tendinum and muttering delirium with extreme prostration until this date, when death occurred. The limb was removed after death and the specimen sent to the Army Medical Museum. [*Specimen* 1000, *Surg. Sect.*] The sphacelus had involved all the tissues for five inches above the divided bone, and there seems to have been a faint effort to form a line of demarcation.

"This was, at first, a very mild case, with no very decided constitutional depression until the system seemed to be poisoned by the absorption of the products of the gangrene, when the ulceration became more rapid, and was finally, as the strength succumbed, converted into uncontrollable and rapidly extending sphacelus, accounting satisfactorily for the unfortunate result. The treatment locally had been, first, weak solution of creasote, made soluble by one drachm of alcohol, four drops to one ounce of water; and second, strong nitric acid, never fully applied, however, to the depths of the diseased tissues. The constitutional treatment was stimulating, sustaining, and tonic.

"CASE VIII.—John Jordan, Private, Co. H, 2d Maine, aged 20 years, was struck at Fredericksburg, December 13, 1862, by a fragment of shell, which passed across the right thigh below Poupart's ligament, through the scrotum, destroying the right testicle, and behind the left thigh, producing in its course very extensive but superficial wounds of the anterior portion of right and posterior portion of left thigh. He was admitted December 26, 1862, and placed in ward No. 5. February 27, 1863, he had febrile disturbance and anorexia, a yellow, furred tongue, an anxious, restless expression of countenance, and a burning pain in his left thigh. There was on the right thigh a granulating surface three by two inches in dimensions, level with the integument, and cicatrizing rapidly. A smaller, equally healthy surface remained unhealed on the scrotum, while on the posterior portion of the upper part of the left thigh an ulcer three by two inches in extent was found, oval in shape, covered with an ashy gray slough, with its margin thickened and everted, surrounded by a livid areola, and, instead of normal pus, discharging a thin fetid serum mixed with débris. He was at once removed to the house; the whole diseased surface was touched with pure nitric acid and dressed with the creasote lotion; stimulants and the best extra diet, with beef essence and milk punch at short intervals, and citrate of iron and quinine three times daily, were ordered. March 5th: The attempt to push the nutrients and stimulants produced, as it generally does, anorexia, nausea, vomiting, and diarrhœa. The tongue became thickly coated with a yellow fur and dry and red at the tip; and so great was the gastric disturbance that all medicines were discontinued and the stomach allowed to recover its tone by rest, no longer being teased either by drugs or excessive and undesired nutriment. No benefit followed the local application, and the ulceration had extended in every direction. There was the characteristic margin,

[1] Space will not permit to introduce all cases cited by Dr. THOMSON. CASES III, IV, VI, and VII have been omitted here.

preceded by the areola of livid stasis, preparing the tissues for their rapid destruction. The connective tissue beneath the skin had been destroyed, so that the skin for one inch from its margin was perfectly movable. The muscles separated from each other by the death of their connective tissue lay in the wound bathed in its discharge, but rosy and florid, and resisting the advance of the disease. This sore was so unmistakably hospital gangrene that several pictures of it were taken by direction of Surgeon Brinton, which represent well the surface of the ulcer dripping with its thin serous discharge, mingled with threads of dead connective tissue, its 'piled-up,' thickened, and everted margin surmounted by a thin line of vivid redness, and its broad zone of purple congestion shading away into a bronze hue, the depth of color in the areola indicating the engorgement of the small vessels and its hue the feebleness and slowness of the movement of the blood. It was determined to try the opium treatment, with hydrochloric acid as a tonic, and this mixture was given in the proportion of 16 drops of tincture of opium with four drops hydrochloric acid every three hours. The sore was dressed with a stimulating poultice composed of flaxseed, cinchona, and ginger mixed with porter. Under the use of the acid internally the tongue has become clean and moist, the tone of the digestive apparatus improved, and a fair quantity of food had been taken. Porter and ale had been given as the stomach would retain them. But little change had taken place in the character of the ulcer, which was eight inches in length by seven in breadth, extending to the perineum, and irregularly oval in shape. The muscles exposed (the semi-membranosus and biceps) had yielded and were now almost divided. The sores on the right thigh and scrotum had not been in the least affected, but were cicatrizing rapidly. The entire surface of the gangrenous sore was now thoroughly cleaned, all sloughs and shreds removed with forceps and scissors, was well dried with lint and carefully painted with pure nitric acid. The brush, charged with acid, was passed beneath the excavated margin in some places more than an inch. The patient was etherized, and this acid application was made most carefully and completely. This was considered a dernier resort, for although the capacity for taking and assimilating food seemed to have been increased by the acid treatment internally, yet his strength was daily diminishing from the exhausting discharge and from the absorption of the products of the gangrene. On the succeeding day an entire change in the sore was observed; there had been no extension of the gangrene, the fetid odor was gone, and the discharge was more consistent and less serous. In a few days more all the shreds of dead fascia were removed, and the surface was found to be perfectly healthy. The contrast between the ragged, offensive, yellow-colored ulcer before the last application of acid, and the florid, perfectly normal granulating surface which replaced it, was as gratifying as it was surprising. With the local there was also a constitutional improvement. The appetite became voracious, the patient slept well; there was no pain, and the process of repair was very rapid. The acid was continued internally. April 1st: The sore was now two by three inches in extent and cicatrizing rapidly; but a small surface yet remained unhealed. The patient was in perfect health, had gained flesh very rapidly, and was now on crutches. There was some contraction of the flexors, as the biceps and semi-membranosus were both involved in the destruction. [Jordan was discharged June 9, 1863, and pensioned. Examiner J. C. Weston reported, September 11, 1869: "At the biennial examination in 1865 atrophy and increased weakness of right thigh and leg had occurred. His gait is always affected; he has severe pain in region of cicatrix of left thigh; this cicatrix is six by three inches, is depressed, indurated, adherent to muscles, and sensitive on account of rigidity and emaciation; he cannot fully extend the leg." His condition had not improved when examined in 1873.]

"The most remarkable circumstance in this typical case is the fact that when the gangrene attacked the granulating surface of the left thigh the equally large granulating surface of the right thigh was unaffected; and that while the gangrene was ravaging the left thigh the rapid cicatrization of the right proceeded uninterruptedly. The discharge from the left thigh was so profuse that no precaution would have prevented the virus from coming in contact with the excoriated surfaces of the scrotum and right thigh. If, therefore, the disease be propagated by inoculation, all the circumstances were favorable; since the proximity of the thighs at their upper part, and a denuded surface on the scrotum, that might act as a link, render it certain that a portion of the great discharge from the left must frequently have been placed in contact with both of the other sores. If, on the other hand, the gangrene be not a local but a constitutional disease, why should it spend itself on one granulating surface when there were two others equally obnoxious? The contrast between these sores was marked; for while the tissues of the left thigh were melting away under one's very gaze, the process of repair in the scrotum and right thigh was progressing as rapidly as under the most favorable circumstances. In its earlier stages this case was twice treated with nitric acid, and perhaps imperfectly, from its not having been carried into the recesses of the ulcer. The system of urging nutrients, stimulants, and tonics irrespective of the natural desires of the patient is, I am satisfied, pernicious. The vital energy being depressed, the digestive organs are enfeebled; and the introduction of milk punch, beef essence, eggnog, and with stimulants porter, ale, etc., into an unwilling stomach, simply produces anorexia, nausea, vomiting, and diarrhœa. The tongue became furred and dry, and there was a perfect disgust for all food. The hydrochloric acid was given to correct this condition; and whether its action was confined to the stomach in rendering soluble the aliment given in very small quantities, or whether its action was catalytic or eliminative, I shall not pretend to state, but under its influence the tongue became moist and clean and the patient made known his desire for food. Nutrients were then given more freely as his appetite returned. The recovery of this man is due, firstly, to the thorough application of nitrid acid to every portion of the ulcer, which changed its specific nature immediately; and, secondly, to the combined effect of acid and opium internally. After the last complete application of acid the sore was changed in character, the areola disappeared, the surface became clean, the margins lost their elevated appearance, the serous discharge became purulent, and the offensive odor was entirely destroyed. An equally marked improvement occurred in his general condition.

"Case IX.—George Zilch (Zuelch), Sergeant, Co. K, 7th New York, aged 25 years, had his left leg amputated at its upper third for a bullet wound received at Fredericksburg, December 13, 1862. He was admitted to Douglas Hospital December 26th,

and placed in ward No. 5. The stump had closed slowly by granulation until there remained an ulcer as large as a half dime on its face. April 14, 1863, this ulcer was inflamed around its edges and covered with a white pultaceous slough; there was no constitutional disturbance, and the patient was allowed to remain on his crutches. The ulcer was cauterized with nitric acid and dressed with solution sodæ chlorinatæ. 18th: The ulceration and areola are both enlarged, and the slough, yet very tough, is thicker. Acid was again used locally. 21st: He is feverish and inclined to nausea; his pulse 120, skin hot, and tongue thickly coated. The ulcer is extending in depth, and he was removed to the gangrene ward. 22d: The solution of bromine was applied to the sore after cleansing the surface as much as possible of the tenacious slough. His general condition was unfavorable, and there was a tendency to diarrhœa and perspiration. Internally he took muriatic acid, with extra diet and stimulants. 24th: Bromine was again applied to the surface and used in the form of vapor. The ulcer was now three inches in diameter, irregularly circular in form, with ragged, everted, and thickened edges, and surrounded by a purple areola. The slough was one inch in thickness, and resisted the action of the bromine. 26th: The sore is looking better; it has been disinfected since the first application of bromine, and the constitutional symptoms are better. 27th: A painting in oil was made to-day by Surgeon Brinton's direction, which would be pronounced a good representation of hospital gangrene. 28th: The slough is much thinner to-day, and the granulations are showing the thin gray covering. 29th: The sore is much better, is becoming covered with granulations, and has lost almost entirely its specific appearance. There is no constitutional disturbance, no fever, no headache, the tongue is cleaning off, and there is a return of the appetite. The bromine vapor was discontinued, and sol. sod. chlorinat. substituted. 30th: The livid areola has been changing daily in hue under the bromine treatment, has now entirely disappeared, and the sore is perfectly healthy. May 6th: He is still improving, and is taking tonics and nutrients. 20th: The sore is reduced to half its original size and is now cicatrizing rapidly. 24th: There is now a surface as large as a penny unhealed; health is very good; he is about the ward on crutches, and is no longer considered an interesting case. This man steadily improved; recovered with a good stump, and was finally sent to New York to be mustered out of service. He was discharged May 8, 1863, and died July 2, 1878, of valvular disease of the heart and cardiac asthma.

"We have in this case another instance in which the acid, locally used, proved useless, and in which the solution of bromine caused an immediate improvement. It was found necessary to apply the caustic solution to the ulcer three times, owing to the thickness of the slough, which was too closely attached to be removed by spatula or forceps. Its action here seemed to correct the fetor at once, to check the molecular death, and to change the hue of the areola, by causing a more healthy action in the capillaries. The gnawing burning pain was relieved, and the patient was able to sleep in comfort. The absorption of the virus produced in the ulcer was prevented by its destruction, and the nervous system quickly regained its tone. I will conclude this brief history by a short summary.

"*Etiology.*—This disease made its appearance in a wooden pavilion containing fifty beds, most of them occupied by very seriously wounded men unable to leave the building, with a cubic capacity of 1050 feet to each bed, heated by ordinary radiating coal-stoves, devoid of any system of ventilation, and having no ingress for pure air nor egress for foul, except through the windows and doors. This want of pure air was combined with a want of strict police and a careless and unscientific method of dressing the wounds, rancid ointments being largely used instead of the ordinary water dressing. No case of gangrene was received as such into the hospital, nor is it probable that it was otherwise introduced. Although a majority of the cases in this ward escaped gangrene, yet there was evidently some depressing agent at work, since but few wounds healed rapidly. The patients seemed also dispirited, homesick, and moody. Those who were attacked were removed to a ward in the brick house, where they were isolated and at the same time placed under better hygienic influences. Two shafts for foul air, connected with the stoves, which withdrew the foul air from near the floor, had recently been placed in the ward by order of the Surgeon General. This was not considered sufficient, and the long doors of these foul-air shafts were kept constantly open. Strict attention to cleanliness and careful dressing was enforced, and what might have been a very severe epidemic was confined to few cases. The upper row of windows were rehung in such a manner as to direct the currents of cold air admitted in a line with the roof, and, to crown all, the ridge ventilation was applied to the pavilion. These precautions, and an improvement in the diet of the house, giving more vegetables and antiscorbutics, enabled me to prevent any further serious manifestations.

"There were three other wards of like construction with Ward No. 5, but two of them were unoccupied and the third one contained fewer and less serious cases. The table on the next page indicates that of the nine unmistakable cases reported, eight appeared in Ward No. 5; and that of these eight, five occurred on the west and three on the east side of the ward. Although these facts would suggest the probability of inoculation, yet I cannot but remember that there were at least thirty-five other wounded men in this ward who escaped, although the disease had been in existence several days before February 17th, when I took charge, and no precautions against contagion had been employed. I shall not attempt to argue here the long-disputed point of contagion or non-contagion, but simply state it as the result of my observation that I saw no well-marked instance of inoculation, while I did see many wounds escape this influence where inoculation was not only possible but probable. Nor was it necessary to invoke the aid of any specific virus, since the

TABLE CLVIII.

Summary of Nine Cases of Hospital Gangrene, showing Date of Attack and Grade of Disease.

No.	NAMES.	WARD.	SIDE.	DATE OF ATTACK.	GRADE OF DISEASE.	RESULT.	TREATMENT.
1	Otto Kossack	5	West	February 15, 1863	Ulceration	Cured	Nitric Acid.
2	L. D Thurston	5	West	February 15, 1863	Sphacelus	Death	Nitric Acid.
3	Samuel Fossett [Fawcett]	5	West	February 18, 1863	Ulceration	Cured	Nitric Acid.
4	C. Underwood	3	East	February 20, 1863	Ulceration, mild	Cured	Nitric Acid.
5	J. [J.] Wick	5	West	February 28, 1863	Sphacelus	Death	Nitric Acid.
6	Patrick Morrissey	5	West	March 6, 1863	Ulceration	Cured	Nitric Acid.
7	J. Jordan	5	East	February 27, 1863	Ulceration	Cured	Nitric Acid.
8	R. W. Plummer	1	Building	March 9, 1863	Ulceration	Cured	Bromine.
9	George Zilch	5	East	April 14, 1863	Ulceration	Cured	Bromine.

NOTE.—Space would not permit to give the details cited by Dr. Thomson of the cases of Thurston, Fossett, Morrissey, and Plummer, referred to in this table.

unfavorable hygienic influences which had surrounded these men from the date of injury, December 13th, and the date of admission into hospital, December 26th, 1862, to February 15th, 1863, were sufficient to produce, in all the cases treated in Ward 5, a well-marked cachexia—neither scorbutus nor anæmia, but more unmanageable than either, and due, most probably, to the absence simply of fresh pure air in sufficient quantities. With no further improvements than those mentioned, a marked change for the better took place in the other inmates of this ward. Their wounds became healthy and healed rapidly, and their spirits became cheerful. It will be observed from the table that I have described two grades of hospital gangrene, the one mild, generally manageable, and characterized by ulceration or molecular death of the tissues, spending itself generally in the subcutaneous and intermuscular connective tissue; the other, more rapid in its course, more fatal, less amenable to treatment, and distinguished by sphacelus or mortification *en masse* of the invaded tissues. It will be seen that, of the nine cases, seven are described as ulceration and two sphacelus, and the latter both fatal. These two cases last mentioned were entirely uninfluenced by the treatment employed. The rapid invasion and advance of the mortification, and the impossibility of reaching it with nitric acid to influence it locally, left but little to do but to observe its profoundly depressing effect on the vital forces. Bromine may prove the antidote in such cases, but its virtues were then unknown to me. Treatment: Recognizing the depressed condition of the first few cases, I endeavored to remedy it by giving, at short intervals, nutrients and stimulants, with such tonics as seemed proper; and milk punch, alternating with beef essence, porter or ale, and eggnog was at first given, regardless of the desires of the patient. The citrate of iron and quinine with sherry wine was given in doses of 6 to 10 grains three times daily. This system was found injudicious, since it overpowered the feeble digestive organs and caused nausea, vomiting, and diarrhœa; it was suspended, and four drops of hydrochloric acid, in combination with 16 drops of tincture of opium, were given every three hours. Under this treatment the tongue became moist and clean, and the appetite returned sufficiently to cause the patient to ask for and enjoy a reasonable quantity of food. The opium was given to allay the gnawing pain and to give rest and sleep, as well as to obtain any specific influence over the disease which it might possess as claimed for it by the older writers. The local treatment consisted at first in the use of undiluted nitric acid freely applied to the entire surface of the ulcer. The table indicates the success of that treatment. Of the nine cases, all were treated with the acid in the early stages. Of these, two were fatal and two resisted the acid—or, in other words, in four cases it was useless. Of these four, the two fatal cases were not treated otherwise, while the other two were treated with success with bromine. The five cases treated successfully with acid are marked ulceration, and were milder than those that proved fatal or those that were treated with bromine successfully. The dressing, after the use of the acid, was an antiseptic wash, either creasote or liq. sod. chlor. in a dilute solution of bromine in water and bromide of potassium, proposed by Surgeon Goldsmith, U. S. V. Two cases were treated with this agent, in both of which nitric acid had failed. One of these would, doubtless, have proved fatal, while the other was progressing rapidly, although the acid had been used several times without benefit.

"The action of the bromine is that of a caustic; all the necrosed tissues are converted into

tough yellow shreds and are perfectly deodorized. The ulceration seems to be checked at once, while the nervous system, no longer depressed by the absorption of the fetid products of the mortification, soon recovers from its depression. The areola loses its livid hue, becomes more crimson, and finally disappears; the sloughs are rapidly thrown off and a rosy, florid surface appears beneath. The bromine was also used in the form of vapor, confined to the surface by oiled silk. Its antiseptic influence is very powerful, since not the least odor could be perceived on dressing these gangrenous sores, even when they had been covered closely with oiled silk for twelve hours. From its antidotal efficacy in these two cases I have formed a high opinion of its value in the local treatment of this disease.

"*Microscopy.*—The discharges from several of these cases were examined to ascertain whether some of the speculative views in regard to the presence of fungi and their influence in producing the disease could be sustained, but no fungi were found. The discharge consisted of fluid, granular matter, and débris. The connective tissue seemed to have been broken down into unrecognizable granular material. The fibrous tissue was softened and easily teazed out, and in the muscular tissue the striated appearance was lost before the fibrous.

"No evidence of textural growth was found in the discharges, although the 'piled-up' and thickened margins of the ulcers would probably reveal, on examination, a multiplication of the connective tissue-corpuscles, as reported in a similar group of cases at Annapolis by Assistant Surgeon Woodward, U. S. A. Since the preceding report was drawn up four other cases of hospital gangrene have been observed, occurring sporadically, and treated with success with bromine. Their clinical histories are very briefly offered for consideration, in addition to those already submitted. No other cases have occurred in this hospital. It will be observed that three of these four cases were fully treated with pure nitric acid without benefit, and that the four did yield eventually to the local application of bromine. Where that remedy has required heretofore several repetitions, it would now be used more energetically. The diseased surface would be thoroughly cleansed of all sloughs by removing those portions dead, yet tenaciously adherent, with the forceps and scissors, and pure bromine would be freely used by means of a glass pipette or a syringe. A number of the cases reported I am now satisfied would have proved fatal but for this local treatment, and it will be a proud satisfaction to Surgeon Goldsmith to know that he has not only already been instrumental in preserving so many valuable lives, but that he has provided the military surgeons with a defence against one of the most deadly and obdurate of his antagonists."

Sporadic cases of gangrene had occurred in the hospitals at Memphis, Tenn., in May, 1863, and during the latter part of this month the number of cases increased so rapidly that, on June 19th, an order was issued for the organization of Church Hospital for the special care of patients afflicted with this complication. The hospital was placed under the charge of Acting Assistant Surgeon C. H. Cleveland, whose detailed report of the progress and treatment of the disease is here appended:

"*General History:* Although I have been at no inconsiderable pains to obtain a history of hospital gangrene as it has appeared in the military hospitals of this city, I am convinced that I have been unable to collect all the facts necessary for a complete history, and therefore shall confine myself mainly to such as fell under my own observation.

"The first cases of this disease which came under my notice were those of Lieutenants Alban, Dallmyer, Letner, and Davis, who were brought to Officers' Hospital, of which I then had charge. They were received from the hospital boat on the evening of May 27, 1863, and each had gangrene of several days' standing when admitted, and were expected to survive but a few hours. In fact, Lieutenant Letner, who had gangrene of the stump of the left leg, died on the 29th, the second day after admission. Although the flaps sloughed away from the stump of Lieutenant Dallmyer so as to leave the bone uncovered for at least two inches, still, the periosteum remained vitalized. The gangrene was quickly arrested by the application of Labarraque's chlorinated soda solution, under the vigilant care of Cadet Randall, who attended to the dressing of the patient. Granulations sprang up all over the surface of the bone, a fine conical stump was formed, and on the 12th of June, about a fortnight after admission, he was dismissed on leave of absence, and went to his home. About this time, and later, a number of cases occurred in the different hospitals, but their

nature was not always understood by attendant surgeons. When attention was especially called to this disease by Surgeon Irwin, Superintendent of Military Hospitals here, cases were found in the Union Hospital to the number of twelve (12) June 25th; and soon thereafter at the Jackson, Gayoso, and Overton hospitals. The surgeon in charge of Adams Hospital reports the case of a man who came from the vicinity of Vicksburg on the 18th of February. He says that is the only case which has occurred in that hospital this year—a statement evidently erroneous, as Corporal Fuller was sent here, from there, with gangrene of right ankle, on the 9th of August. A similar error occurred in the report of the surgeon in charge of the Webster Hospital, who says but one case has occurred in his hospital; and yet he has sent to us Privates Alt, McEvoy, Cloud, McClure, and Butler, all with unmistakable gangrene. From the Overton Hospital we have received fifteen (15) patients, and how many more have had the disease in that hospital I am unable to determine, as I get no response to my applications for information. From the Jackson Hospital we have received eleven (11) patients; but from that hospital also have been unable to obtain any further information.

"Up to the first of September forty-six (46) patients have been sent to us, from other hospitals, having gangrene, which I have reason for supposing are not more than half the cases that have occurred in the hospitals. I know of seven (7) cases occurring at the Officers' Hospital which were retained there for treatment, as we have no special accommodations for officers.

"Not only have there been manifest errors in the reports from different hospitals in regard to the number of patients who have had gangrene, but the date of its appearance has been incorrectly reported. Early in the months of June the wards of Union Hospital were filled with patients from down the river, and immediately Cadet Randall reported to me that gangrene was among them. Surgeon Irwin states that, according to information in his possession, gangrene appeared *first* in the Union, then in the Jackson, the Gayoso, and the Overton hospitals; and his order for organizing and opening Church Hospital was issued on the 19th of June, one week before the disease was *reported* to have appeared in Union Hospital. The order for establishing and opening this hospital was issued on the 19th of June; yet, owing to delays in the Quartermaster's Department, no patient was received until the 30th of July, and the two days of that month are included in the report for the month of August. During its organization and until the 7th of August I was in charge of this hospital, when Surgeon George K. Weeks was assigned to its temporary charge for the special purpose of testing the use of bromine in the treatment of gangrene. Until Surgeon Weeks came we had no bromine; one ounce had been furnished to the hospital, but after the dressers had used it once it unaccountably disappeared. After that time reliance was placed mainly on the local use of Labarraque's solution of chlorinated soda applied in its full strength, although nitric acid, acetic acid, sulphate of zinc, and muriated tincture of iron were used in some cases.

"The favorable result which followed the chlorinated soda preparation in the case of Lieutenant Dallmyer at Officers' Hospital gave me considerable confidence in it, both in gangrene and erysipelas, which confidence is shown by the hospital records not to have been misplaced, as every case of erysipelas sent to us was cured by it alone in from three to five days. Private Samuel Arbothnot was sent here from Jackson Hospital, with gangrene in the palm of the left hand, July 30th, and was returned cured of the gangrene August 8th. Robert Graham was admitted from Union Hospital on the 31st of July, with gangrene of the right arm, and returned with no vestige of gangrene remaining on the 4th of August. Private William Goff was admitted from Union Hospital, August 1st, with gangrene of the right leg, and returned cured August 4th. Private T. L. Twiman was sent here from the Overton Hospital on the 31st of July, with gangrene of the right thigh, and returned cured of gangrene on the 5th of August. Private Fred. Louis came from Jackson Hospital, with gangrene of the right hand, on the 30th of July, and was returned cured on the 4th of August. Other similar cures have followed the persistent use of this remedy since that date.

"On the 8th of August, when Surgeon Weeks took charge of the treatment, he brought from Surgeon Irwin five ounces of pure bromine, which supply was exhausted on the 16th of August, and no more has been had since. On the 20th of August, Dr. Warriner, agent U. S. Sanitary Commission, gave to the hospital five bottles of Professor J. Lawrence Smith's compound solution

of bromine, which is now used in place of the pure article, but not to the satisfaction of any one connected with the hospital, it evidently being by no means equal in efficiency to the bromine in full strength. During the week that pure bromine was applied it was found, as the records show, that usually a single application sufficed to completely eradicate the gangrene. In cases of apparent failure it was afterwards found that there were some parts, deep between muscles, under the integuments, or in sulci or sinuses, which the bromine did not reach. While we had no bromine, and also when we had only the Smith's compound solution, we found it much more difficult, and in some cases quite impossible, to eradicate the disease, mainly from the impossibility of bringing the remedies directly in contact with the entire affected surface. Up to the 1st of September forty-six (46) cases of genuine hospital gangrene have been treated in this hospital. Of that number thirteen (13) died, but none directly from the gangrene. During the month fifteen (15) have been cured and transferred to the hospitals from which they came. Eighteen (18) still remain under treatment, most of whom are entirely free from gangrene, but are not restored in health sufficiently to leave the hospital. Some of these will die from the *effects* of gangrene on the system.

"*Diagnosis.*—Hospital gangrene, as it has been presented to us at this hospital, has assumed a great variety of appearances. In the earlier stages it has appeared as a dusky, almost black, mass of dead and rotten flesh, occupying the seat of the disease, surrounded by a reddish ring of slightly swollen integuments, which ring varies from one to five lines in breadth, while the adjacent tissues do not appear to be affected by the disease, except that they, as well as the whole body, contain less heat than is natural in healthy structures. Often the disease has burrowed under the integuments bordering a wound, and when the skin dies it loses its epidermis, the true skin becomes reddish, greenish, purplish, or black. When a surface already divested of its skin is affected with the disease (and most of the cases at this hospital are truly traumatic), the first invasion appears by giving to the surface an ashy-gray color, with a pultaceous consistency, and the *peculiar* odor of spoiled meat, by which the disease is readily recognized. This pultaceous ashy appearance of the surface wounds presents itself when the areolar tissue alone is attacked. When the muscular tissue becomes affected, and when small blood-vessels have become ruptured, a dark, grumous, almost black, dirty appearance of the diseased surface is presented, accompanied by a powerful fetid odor, and, usually, with an invasion of the disease under the skin, and between muscles and tendons in the connective tissues much beyond the boundary of the disease as it appears on a superficial examination. In the case of Private Milseps, who was wounded at Port Hudson, on the 27th of May, with a minié ball in the right thigh (the ball not being extracted till he came here), the disease burrowed in the fascia of the thigh until his whole thigh appeared gangrenous in the deep-seated parts, and he died suddenly from arrest of circulation. *Post-mortem* examination revealed a detached thrombus in the left auricle of the heart, plugging up the artery, which weighed four hundred and eighty-two (482) grains. One patient, Private T. D. Riggs, who was wounded high up in the right calf by a musket ball, at Helena, on the 4th of July, and brought here on the 31st, had the disease following down the tendon to the os calcis, which was necrosed. Although the entire extent of the leg was laid open it was too late to save the patient, who has since died (Sept. 2d) from the absorption of gangrenous matter. I removed from his thoracic duct a thrombus nearly six inches in length. These two cases are but extreme illustrations of the tendency of the disease to extend itself in the areola tissue, along plains, and between more solid organs and structures. But muscles, vessels, nerves, tendons, periosteum, and bone are often invaded, when the part affected turns dark, emits a peculiar (gangrenous) odor, dies, softens, and finally liquefies when not removed in the form of slough or by the dresser's instruments.

"*Preparation of Wound.*—I am convinced that many surgeons have failed in the treatment of hospital gangrene because they have not fully perceived the necessity of thoroughly cleansing the wound of all dead and diseased matter previous to the use of any local application. Private James McEvoy, who was wounded at Raymond, on the 12th of May, and had his right arm amputated near the elbow, had gangrene of the stump about the 20th of June, and was sent here on the 10th of August, with a statement that bromine had been applied, daily, for eight days. On examination it was found that there were at least two inches in extent of dead structure on the end of the stump, and the bromine had been applied to that, and not to the live tissue. All the dead and dying structures were carefully dissected from the surface of the stump, removing a large quantity

of putrescent matter, and then bromine in full strength was cautiously applied to the entire surface, and the disease was at once arrested. He remained ten days, and then was returned to Webster Hospital.

"When patients are first brought here it is often necessary to place them under the influence of chloroform while their wounds are being prepared, and obtund the pain caused by the remedies applied; and afterward it is not refused them if the dressing is likely to be very painful. The wound is washed by means of a stream of water projected from a syringe; all the pultaceous and gangrenous matter removed with soft cloths; the more tenacious diseased portions taken away with forceps, the scissors, and scalpel; and finally, all blood, water, moisture, and semi-fluid matters under the skin, or between muscles or tendons, are removed with a little swab made by winding a strip of soft cloth around a stick. . If the disease has burrowed under the skin it is better to at once open up all such retreats, as well as to carefully pare off the diseased portions of the skin on the edges of the wound, that the agent applied may come directly in contact with the vitalized structures in the parts affected. If, through carelessness or oversight, this thorough preparation of the wound is not attended to, the progress of gangrene is not likely to be stayed whatever the remedy applied.

"Soapsuds as a wash does not answer for gangrenous ulcers as well as pure warm water. It appears to combine with the fluids of the surface, producing a slimy mixture which it is difficult to remove. A diluted solution of Labarraque's chlorinated soda has been found to answer admirably in these cases, for when applied in a gentle stream from a syringe it can be made to penetrate into all the recesses of the disease, destroying all odor and dissolving and removing some of the dead matter attached to the surface of the ulcer. At about the strength of sea water it seems to properly stimulate the structures as well as cleanse them. An ordinary hard-rubber syringe with the little swabs (already described) have been found preferable to sponges or cloths for cleansing tender and delicate surfaces.

"*Local Applications.*—Any substance which has the chemical power of decomposing the specific virus of gangrene so that it no longer exists as gangrene must possess the property of a curative agent in this disease, provided it can be brought in sufficient quantities in direct contact with every atom of gangrene matter; and provided also that it does not possess sufficient power to overcome and destroy the vitality of such still vitalized structures and tissues as we wish to preserve. We have made trial of nitric acid until we have become satisfied of three things in regard to it: It will destroy all gangrenous matter with which it is brought in contact in its full strength. It is, however, extremely difficult in many cases to apply it in full strength, as in sinuses and sulci, where the moisture in those parts may so dilute it as to render it inefficient. It is unsafe, as, if brought in contact with the fine tissues, nerves, vessels, periosteum, or bone, it is almost certain to cause destruction to the parts and produce irreparable injury.

"Sulphate of zinc in solution does not appear powerful enough to arrest the disease in many instances. Acetic acid has not been applied in a sufficient number of cases to have led to any positive conclusion. The same may be said of the solution of the chloride of zinc. The muriated tincture, as well as the solution of the persulphate of iron, have both been used, but principally on bleeding surfaces and to check hæmorrhage from ruptured vessels; and while they may have a curative power, such property has not been so manifest as to give us much confidence in them as arresters of gangrene.

"Labarraque's chlorinated soda solution has proved quite efficient, applied in its full strength, as an arrester of gangrene. In all cases where the liquid could be thoroughly applied to all of the affected parts, one, or at most two or three, applications appeared to eradicate the disease. But it could not always be applied to deep-seated parts, or within sulci, without becoming diluted with the fluids already there, and so much of the solution seemed to be demanded that it was liable to flow beyond the ulcer and the healthy skin be blistered by it. But, during nearly one-half the time this hospital has been open, we have placed our main reliance on this agent, and our confidence has not been shaken. In all cases of ulceration, where no gangrene remains, we wash the surface once or twice a day with this solution, diluted, and saturate the dressings with it as often as they get dry, or once in two hours, and are well pleased with the result.

"Bromine in its full strength, however, is the agent which has given us the most satisfaction. This does not appear caustic enough to destroy healthy tissues, but is of sufficient strength to

unite with and change all the parts affected with disease. Of course a few drops will not unite with or change a large amount of gangrenous material, but in all cases under my observation where the dead matter had been properly dissected away and the wound cleansed of its pultaceous and other dead matter with the syringe, the forceps, and the swabs, and the surface dried with soft cloths, one application, or at most two or three, has obliterated all traces of gangrene and left the wound a simple ulcer. As has been observed, the wound must be thoroughly and carefully prepared before the bromine is applied. Even if all other necessary conditions are complied with, should moisture be allowed to remain in the deeper parts of the sore, that moisture may so dilute the bromine as to render it inefficient, or it may protect the subjacent parts from the remedy, and a point of gangrene will remain to infect the whole sore. Bromine can be conveniently applied by means of little swabs, like those used in cleansing the wound. First, there should be prepared and at hand a cloth spread with simple cerate, large enough to more than cover the affected surface. The ulcer should be cleansed and dried, and then an attendant, standing near the patient, holds the phial of bromine, from which he removes the stopper just long enough to allow the surgeon to insert into it a little swab, saturating it with the bromine, which is at once applied to the ulcer. This operation is to be repeated until all parts of the sore are touched with the bromine; and to parts beyond the reach of the swab bromine should be injected by means of a glass P. P. syringe, when the sore should be immediately covered with the cerated cloth to prevent evaporation of bromine and to protect the ulcer from the atmosphere. Then the part may be dressed with cloths and bandages the same as for simple sores.

"The pain which attends and follows the application of bromine is quite severe, but not more severe nor of longer continuance than follows the application of milder agents. The sense of pain appears even somewhat obtunded by the action of it, and after a short time patients express themselves as being much easier than they have been for days.

"To surgeons and attendants bromine, when incautiously used, proves very disagreeable, and this fact, doubtless, has prevented its use in many cases. If the vapor of bromine is allowed to come in contact with the eyes and air passages such parts suffer severely from irritation for several minutes, then all unpleasant effects pass away. But, with proper precaution, these parts need not be exposed to the vapor, and ten or twenty patients may have bromine applied to them in a morning without much discomfort to the surgeon.

"Whatever agent is applied to a gangrenous surface it does not appear desirable to disturb the dressing more than once a day. When bromine is used it is usually necessary to wait two or three days for the surface of the sore to become thoroughly cleansed before it is again resorted to; but if there remains a decidedly gangrenous odor on the second day, or if it appears at any future time, the parts should be carefully examined and bromine applied to all affected surfaces. Gangrene can be detected by the trained sense of smell more readily than in any other way, and for several days after the disease has disappeared wounds should be examined in this manner, as well as by the eye, and all appearance of taint followed to its source and the disease eradicated.

"On the second day, usually, after bromine has been applied the surface of the ulcer looks dark and charred; on the third day the dead portions begin to liquefy; and the fourth day the surface appears studded with healthy granulations. After the gangrene is subdued the wounds are dressed as simple ulcers, but in most cases the dilute chlorinated soda solution is constantly applied, both as a slight stimulant to the newly formed tissues and to protect it from the virus which may be in the atmosphere of the hospital. I have made considerable use of oakum, wet with a solution of chlorinated soda or of the chloride of lime, to gangrenous ulcers *the day after* the application of bromine, and to the ulcer after the wound is freed from gangrene, and am satisfied that, in general, it is preferable to lint. It is easy of application, readily absorbs the excretions, and is easily removed when the wound again requires dressing. A very convenient way of applying moisture to the sore is by means of a hard-rubber syringe. The solution may be drawn into the syringe, the pipe of which can readily be inserted under the bandage and the liquid applied directly to the oakum, filling and covering the ulcer and moistening the entire dressing. The compound solution of bromine has been extensively used by us since our stock of pure bromine became exhausted, but we do not consider it a good substitute. It does not appear to be active enough to readily destroy the gangrene. It has been applied day after day carefully, thoroughly, and faithfully, with the swab and the syringe, into parts where the gangrene has burrowed under fascia and

along tendons, as it is very apt to do, and directly to the walls of such extensions, when they have been laid open, by means of pledgets of lint saturated with it, as well as in the same manner to the original ulcer, and yet we have sometimes failed for days to arrest the disease. I have made careful trial of both the compound solution of bromine and Labarraque's solution of chlorinated soda, and cannot discover that the bromine preparation possesses any valuable properties which the chlorinated soda has not. Both destroy the disease when applied to it, but the compound solution of bromine causes more pain, does not appear to be any more active than the chlorinated solution in full strength, and very readily loses its bromine by evaporation if not quickly and cautiously covered with a cerated cloth.

"Pure unadulterated bromine seems to possess special properties which entitle it to more confidence than any other agent with which we are acquainted. The liquid readily vaporizes in the atmosphere and the vapor is easily absorbed by fluids. The vapor when brought in contact with the odoriferous emanations of gangrene at once destroys their odor, and probably their specific gangrenous character. When thoroughly applied in sufficient quantity to a gangrenous sore it at once obliterates all gangrenous odor, and no gangrene appears afterward, unless the wound receives new infection. Its ready vaporization permits its application to the bottom of sinuses and sulci which cannot safely be laid open with the knife, and which are very common in the patients of this hospital; its prompt, almost instantaneous, action precludes the necessity for a prolonged use of the remedy; while sufficient experience in its use shows that it may be applied directly to the covering of a nerve, or the periosteum, without destroying their vital integrity.

"*Contagiousness.*—Hospital gangrene is produced by infection upon an exposed surface. Several cases have come to us with the disease following the application of a blister. It has also appeared in bed-sores. One case, where the arm had been broken, badly adjusted, and splints caused abrasion, gangrene followed. A man acting as nurse to his captain who had gangrene, had small spots of inflammation on his ankle, caused possibly by mosquito bites, which he had rubbed the skin from; he also had little scratches on his fingers; gangrene set in at all these points, and he may yet lose his life as the result. In Officers' Hospital, an officer with gangrene occupied a room alone; the carpenters wished to put a water-pipe in it, and he was removed to a room in which were three other officers with wounds not then gangrenous; all four had their wounds exposed and dressed, and the gangrenous odor pervaded the apartment. Although the officer was returned to his own room in an hour, the next day gangrene appeared in the wounds of the three others who had been exposed to the infection.

"Instances have occurred in this hospital where wounds which had been free from gangrene for several days became again diseased, and doubtless from renewed infection received from others laboring under the disease. To guard against infection we have made free use of chlorinated soda, chloride of lime, a solution of the permanganate of potassa, chlorinum, and bromine, and the most scrupulous cleanliness and free ventilation. Each patient is supplied with his own drinking-cup and other utensils, and his own sponges; if he has two wounds and only one is gangrenous, each wound has its sponge, and all are kept as clean as possible. If the nurses, dressers, or surgeons have wounds or abrasions on their hands, bromine is applied and their hands exposed to the virus without fear. In cleaning a very bad gangrenous sore the scissors were found to be dull, and while sharpening them I cut out the ball of my left fore-finger; I applied bromine, and the wound healed kindly and readily. Nearly every day I have had either cuts, pricks, scratches, or other abrasions on my hands, which are freely exposed in dressing the wounds and in the dead-house, with no unpleasant consequences. I have always applied bromine to the denuded surface before exposure, and am convinced that the virus of the dead-house, as well as other animal poisons, is entirely destroyed by the action of bromine.

"*General Treatment.*—The constitution seems to require much more than the ordinary amount of nutriment in this disease, and it is only after considerable poison has been absorbed, and the heart and lungs have become affected, that digestion and assimilation are deranged. It is true that the *temperature* of the entire body is, almost invariably, below the normal standard. During the month of August the thermometer ranged, in the wards of this hospital, at 2 o'clock P. M., at from 98° to 103°, and yet the average temperature of the patients at the same hour, as indicated by the thermometer in their axillæ, was but 89°. The average daily temperature of Sergeant

Wilkie, who died from pyæmia after secondary hæmorrhage, was only 74°; and that of Private T. D. Riggs, who had gangrene of the right calf extending down the tendon to the heel bone, was only 84°. The pulse of the former averaged 114, the latter 88 beats in a minute. This low state of temperature led us to very free use of alcohol in the various forms of ale, porter, whiskey, and brandy, usually given once in two hours, and as much nutriment, beef, eggs, etc., as the patient would take. A very marked desire for acids prevailed, which was gratified by giving pickles, citric acid drinks, and acid fruits. After the disease had progressed to the serious invasion of the general system (and most of our patients were *old* cases, brought from other hospitals) a very persistent diarrhœa was common, and that was about the only condition that demanded active medication. We carefully avoided the use of cathartics and opium, and as a soother to nervous and febrile excitement used Hoffman's anodyne. In some cases, distinctly complicated with miasma (and many of the patients came from the vicinity of Vicksburg, where they had been exposed for months), we gave sulphate of quiniæ—one or two doses of ten grains each were usually sufficient.

"*Conditions favoring the appearance of Gangrene.*—While no certain *cause* for the disease except contagion has been determined, it is evident that a depression of the vital forces has been favorable to its accession. Fourteen (14) out of forty-six (46) cases of our patients were secession prisoners, and I think that all the seven at Officers' Hospital were also prisoners—a much larger number than a fair proportion, proving that exposure, privation, and a consequent depression of vital forces is a condition favoring the appearance of the disease.

"*Post-mortem Appearances.*—The tables compiled from the hospital records, and the reports of individual cases furnished by Cadets Gunn and Lloyd, together with the learned and able report on the pathology of the disease by Surgeon Weeks, who has had unusual opportunities for the study of gangrene at Louisville, Vicksburg, and this place, obviate the necessity of extended remarks on this branch of the subject. With one or two exceptions we have made examinations in every fatal case and have observed a very uniform set of conditions. In all we have found thrombi in the heart, some of which have been very large. In one we found a thrombus in the thoracic duct, and I regret that we did not examine that passage in the preceding cases. In one case of long standing the heart thrombus was softening, and the walls of the heart were tainted with gangrene. In another case, where the disease was of still longer duration, the heart thrombus was considerably broken down and liquefied, and the walls of the heart very much softened, flabby, and decidedly gangrenous. The lungs in every case were spotted with dark specks, and, being cut into, it was found that the smaller arteries were often filled with thrombi and dark matter, evidently the débris which had been washed away from a thrombus in the heart and become lodged in the smaller vessels. The disease in this case was unusually malignant and rapid. In no case have I perceived any collection of pus or softening of matter, such as is said to have been observed in the lungs of those who have died of gangrene elsewhere.

"*Curability of Gangrene.*—This disease, like syphilis in its earlier stages, seems to be entirely local, and completely curable when the parts affected are not *vital* organs, which has never been, primarily, in any case coming under my observation, and when all the parts affected can be reached by direct application of the remedy. But the *secondary* affections, as the thrombi in the heart, the pulmonary complications, and the change in the fluids, which is sometimes called *pyæmia*, are conditions which do not seem controllable by remedies. We have often had cases recover after the heart, the lungs, and the blood had become seriously implicated. But gangrene can be considered certainly curable only in cases where the system has not become seriously affected by disease. In all simple cases gangrene seems as curable as a burn, scald, or any other serious wound.

"*General Treatment.*—No remedy has yet been presented to us that has apparently any marked or positive curative power over the constitutional and organic derangements produced by the absorption of the poison of gangrene. We saturate the air of the wards of this hospital with chlorine, and we have given bromine internally for days and weeks; and while we do not know of a certainty that this course has proved beneficial to our patients, we should hesitate to deprive them of even the possible benefits arising therefrom. Pure air, full nutrition, alcoholic preparations repeated as often as once in two hours, hope, cheerfulness, and immediate removal of all causes of distress and fretfulness (for gangrenous patients are very childish), with perfect cleanliness of the bed and the person, seem preferable to any form of perturbative medication."

The largest number of cases of gangrene (1,611) occurred in 1864, when the terrible battles of Grant in Virginia, and of Sherman in Georgia, filled the hospitals to overflowing; but the disease seems to have lost its terror to the medical officers. The cases were quickly isolated in hospitals or wards specially assigned to this purpose, and under the various treatments described in the preceding pages the larger proportion of the cases were brought to successful terminations. The proportion of cases of gangrene to the number of troops engaged or to the wounded treated in hospitals during the six months of 1865 was very small, only one hundred and thirty-five (135) being found recorded on the registers. Illustrations of hospital gangrene will be found on the plates opposite pp. 739 and 928 of the *Second*, and on PLATE XXVII, opposite p. 53, of the *Third Surgical Volume.*

Instances of *Dry Gangrene*, the result of shot injuries, were rare. A case of this nature has been detailed on page 310 of this volume (Case of E. Green), and another (Case of H. Strauss) has been referred to in *Note* 2, on page 351 of the *Second Surgical Volume.* The appearance of the feet in the latter case is shown in the chromo-lithograph opposite. In these, as well as in the following seven instances, the gangrene was due to impaired arterial circulation:

CASE 1209.—Private W. Steel, Co. G, 70th New York, aged 26 years, was wounded in the left leg, at Manassas Gap, July 23, 1863, and entered Lincoln Hospital, Washington, one week afterwards. Assistant Surgeon H. Allen, U. S. A., recorded the following description of the injury: "The ball struck on the outer side of the leg, passing in a straight line inward through the upper part of the belly of the gastrocnemius, and coming out on the inner side of the calf. The bleeding was copious. Immediately after the reception of the wound the man experienced a severe pain in the ankle and was totally unable to walk, only dragging the limb after him. When admitted into Lincoln Hospital the foot had become bluish, which appearance the patient stated had come on two days previously. The pain in the ankle passed off the first evening, but when the blueness commenced the pain reappeared and continued to increase in severity until the date of amputation. The color of the foot was that of bluish stone, but not shrivelled, the toes being of a deeper hue than the rest. This appearance gradually increased up to the ankle, and then ran up posteriorly to the lower third of the leg. Amputation through the wound was performed by flap method on August 3d. After the operation the constitutional symptoms, such as pale and tremulous tongue, quick and feeble pulse, continued about the same. The flaps were pale and rather flabby, but not gangrenous. A diarrhœa set in, which was checked by August 25th; appetite capricious. By October 20th had entirely recovered, the stump having healed without exfoliating any bone." On January 30, 1864, the patient was discharged from service and pensioned, and subsequently he was furnished with a "Palmer" artificial leg. In his application for commutation the pensioner describes the stump as being in a healthy condition. He was paid December 4, 1880. A representation of the gangrenous limb is given in PLATE LXXIX, opposite p. 818.

CASE 1210.—*M. A. Gammel*, Co. G, Arkansas Regiment, aged 23 years, wounded at Antietam, September 17, 1862, by a fragment of shell just above left ankle. Leg was amputated about two weeks afterwards. On October 28th he was admitted into hospital at Frederick, Maryland. Patient suffered from a large bed-sore, and sloughing of the flaps allowing the bones to protrude; he had also a violent diarrhœa. These complications were alleviated by treatment, but his general condition continued very poor; the discharge from the stump became thin, watery, and dark colored. On December 2d dry gangrene set in, in the great toe of the right foot and also in the second toe. Pulse very feeble and rapid. General condition bad. December 4th: Gangrene involved all the toes; no constitutional symptoms developed; strength very feeble. The patient died December 5, 1862.

CASE 1211.—Private Charles Hanford, Co. I, 14th Ohio, was wounded at Chickamauga, September 19, 1863. The missile entered over the anterior border of the sterno-mastoid of the right side opposite the larynx, passed backward and inward, striking the spine and comminuting its processes at that point. Another ball passed through the right hand at the middle of the carpo-metacarpal articulation. A few spiculæ were removed from the wound in the neck. He was admitted on September 30th into the hospital at Chattanooga, Tennessee. There was complete paralysis of the lower extremities and of the right arm; unpromising case. Simple dressings were applied and anodynes given. October 3d: Large slough of skin on dorsal aspect of left foot; dry gangrene of toes of same side. No other change. Right carotid seen pulsating through wound; little reduction of general heat of body. No trace of motion in extremities and right arm; slight in leg, but being pricked with a pin said it was water falling on the part. October 6th: Motion slight in both extremities and right arm; sensibility increased; can detect pricking in leg and feet. Gangrene of toes progressing slowly; ball of right toe involved; right hand and arm swollen. Patient died October 6, 1863, with tetanic symptoms.

CASE 1212.—Walter Hill, freedman, was admitted into Freedmen's Hospital, Vicksburg, Mississippi, April 26, 1865, with a gunshot wound of the left leg, accidentally inflicted on April 15th. A conical ball entered the left popliteal space and lodged in the deep-seated tissues of the joint. Simple dressings were applied. The bullet was cut out on April 26th. Patient died May 20, 1865, of chronic diarrhœa and dry gangrene of the leg.

CASE 1213.—Private W. J. Logan, Co. K, 9th Pennsylvania Reserves, aged 23 years, received a shot wound of the left foot, at Bull Run, August 30, 1862. The bullet entered the front of the heel and passed directly upward through the top of the foot. Many pieces of bone were extracted. The patient was discharged from service at Carver Hospital, Washington, November 5, 1862, and pensioned. Dr. John Kirker, of Pittsburg, reported, April 15, 1870, that on December 23, 1869, he "amputated the

DRY GANGRENE OF THE FEET.

LIBRARY
OF THE
UNIVERSITY
OF
CALIFORNIA

left leg at the junction of the upper and middle thirds because of dry gangrene of the foot produced under the following circumstances: He received a gunshot wound of the foot which so injured it as to compel him to rest chiefly on the heel in walking, causing, in my judgment, aneurism, which gradually developed during the summer of 1869. Dr. A. M. Pollock operated for aneurism in my presence. Dry gangrene resulted from impaired arterial circulation, it commencing in the original wound, and had involved the whole foot at the time the operation of amputation was performed." The pensioner was paid in June, 1876.

CASE 1214.—Private Peter Mon, Co. E, 2d Massachusetts, aged 27 years, was wounded at Chancellorsville, May 3, 1863. On May 7th he was admitted into Douglas Hospital, Washington. A minié ball had entered the internal portion of the calf of the right leg, lacerated the posterior tibial vessels, comminuted both bones, and lodged in the gastrocnemius muscle. When admitted to the hospital his general condition was tolerable, and the injury to the vessels was not detected, as the heat and appearance of the foot were good. On May 9th it was noticed that dry gangrene was beginning in the foot, and, after free stimulation during that day, a circular amputation was done in the lower third of the thigh by Assistant Surgeon W. Thomson, U. S. A. The patient reacted well and had no bad symptoms from the moment of the amputation. The ligature around the femoral artery separated on the tenth day, and by May 22d nearly one-half of the flap had united. A slight tendency to diarrhœa was readily checked by laudanum enemata. The patient was discharged August 26, 1863; stump quite well; patient strong and hearty.

CASE 1215.—Private W. Thompson, Co. H, 69th New York, aged 19 years, was admitted into Armory Square Hospital, Washington, April 1, 1865, with a shot wound of the posterior aspect of the right leg, received at Hatcher's Run, March 25, 1865. The ball passed upward and made its exit over the tibia five inches below the knee joint. Dry gangrene existed at the time of admission, owing to the circulation to the foot being cut off. On April 2d Surgeon D. W. Bliss, U. S. V., amputated the limb at the lower third of the thigh. Pyæmia supervened on April 12th, and the patient died from exhaustion April 15, 1865.

In all these cases the feet or the toes were the parts affected. As already stated, interference with the arterial circulation was the cause of the gangrene, although the manner of this interference may not be so clear in one or two of the cases. In the cases of Steel, Thompson, Mon, Hill, and Green, the arteries of the affected limb had been injured. In the case of Logan (CASE 1213), dry gangrene developed upon the formation of an aneurism following a shot wound of the dorsum of the foot. In Hanford's case (CASE 1211) complete paralysis of the lower extremities and dry gangrene of the toes of the left limb were the results of a shot injury of the neck with lesion of the spine. In the case of Strauss, phlebitis and dry gangrene ensued after a shot perforation of the pelvis with injury of the urethra. *Gammel* (CASE 1210) received a shell wound just above the left ankle; the leg was amputated; sloughing of the flaps and bed-sores followed, and thirty-five days after the operation dry gangrene appeared in the toes of the *right* foot. The patient died.

In five of the nine cases of dry gangrene here cited, amputation was performed after the appearance of the affection; four recovered. The remaining four cases, in which no operative interference was resorted to, proved fatal.

TRAUMATIC ERYSIPELAS.

Less frequent than the instances of gangrene were the cases complicated by traumatic erysipelas. Under traumatic erysipelas have here been considered the cases in which inflammation of the skin, originating from a wound, quickly extended over the surrounding parts, ending in rapid resorption, while the progress was accompanied by an exceedingly high fever. Cases of acute suppuration and diffuse inflammation, or of diffuse acute osteomyelitis, which have sometimes been classed with erysipelas, are not considered in this group.

The total number of cases of traumatic erysipelas was one thousand and ninety-seven (1,097), or only 0.4 per thousand of the two hundred and forty-five thousand seven hundred and ninety (245,790) cases of shot wounds recorded during the war. With regard to the various regions of the body, the cases were distributed as indicated in TABLE CLIX, on the next page.

The percentages there given, viz: 14.0 per cent. for the head, face, and neck, 5.2 for the trunk, 41.7 for the upper extremities, and 39.1 for the lower extremities, only indicate the relative percentage of the frequency of the disease in the four subdivisions of the body in regard to each other. The liability of the various portions of the body to this infection

TABLE CLIX.

Numerical Statement of One Thousand and Ninety-seven Cases of Traumatic Erysipelas.

SEAT OF INJURY.	CASES.	RECOVERY.	FATAL.	UNDETERMINED.	REGIONAL PERCENTAGE.
Head, Face, and Neck	154	107	44	3	14.0
Trunk	57	23	33	1	5.2
Upper Extremities	457	259	180	18	41.7
Lower Extremities	429	229	193	7	39.1
Aggregates	1,097	618	450	29	

is shown by comparing the number of wounds of each region with the number of cases of erysipelas reported therein. In twenty-six thousand four hundred (26,400) cases of shot wounds of the head, face, and neck, erysipelas was noted in one hundred and fifty-four, or in 5.8 per one thousand; in forty-five thousand one hundred and eighty-four (45,184) wounds of the trunk, in fifty-seven, or in 1.2 per one thousand; in eighty-seven thousand seven hundred and ninety-three (87,793) wounds of the upper extremities, four hundred and fifty-seven, or in 5.2 per one thousand; and in eighty-six thousand four hundred and thirteen (86,413) wounds of the lower extremities, in four hundred and twenty-nine, or in 4.7 per one thousand. It would seem, therefore, that erysipelas occurred most frequently in wounds of the head, face, and neck, next in wounds of the upper extremities, then in wounds of the lower extremities, and least frequently in wounds of the trunk. The prevailing opinion that erysipelas is most frequently found after wounds of the head and face is here corroborated; the frequency of erysipelas after wounds of the upper extremities has also been noted by Socin, who was unable to assign any plausible cause therefor.

The average duration of the disease was eleven days;[1] in 31.7 per cent. it subsided in from one to five days, in 31.7 per cent. in from six to ten days, in 19.4 per cent. in from eleven to fifteen days, and in 17.2 per cent. the duration of the disease exceeded fifteen days, as in the following case, in which it continued for about four weeks:

CASE 1216.—Private *G. Walker*, Co. A, 9th Louisiana, was wounded at Gettysburg, July, 1863, and was admitted on July 18th into the Louisiana Hospital at Richmond; a minié ball fractured the crest of the left ilium; the ball remained embedded in the bone and was extracted. On admission the wound had a healthy appearance and the general condition of the patient was good. On the 22d and 25th of July several loose spiculæ were extracted. On July 28th erysipelas appeared around the wound and gradually spread upward and downward until the whole abdomen, back, and chest were invaded. It there seemed to limit itself. At the first manifestation of the disease an active purgative was administered, and immediately after tincture of iron was given, twenty drops every two hours. An ointment of sulphate of iron, a drachm to an ounce of lard, was used morning and night on the whole surface affected with erysipelas. In spite of this treatment the disease, which seemed to have stopped spreading, extended to the neck, arms, and thighs. The fever increased considerably and was accompanied with delirium and great restlessness, soon followed by coma and prostration; there was also some diarrhœa; two blisters were applied to the inner part of the thighs; carbonate of ammonia, camphor, and bark, with astringent enemata prescribed in addition to the tincture of iron. In order to check the progress of the erysipelas, which threatened to invade every part of the body, a bracelet one and a half inches wide was made by cauterizing with nitrate of silver around the forearms and upper part of the legs. This treatment seemed to check the disease. August 25th: The erysipelas did not spread beyond the line of cauterization, and did not invade the head. Consciousness returned; the bowels became more regular, and the patient, after having been in a very critical condition, and although now (August 25th) very weak, is gradually but steadily recovering; the wound has a healthy appearance and discharges but moderately.[2]

[1] SOCIN (A.) (*Kriegschirurgische Erfahrungen gesammelt in Carlsruhe* 1870 *und* 1871, Leipzig, 1872, p. 34) found that the average duration of the cases observed at Carlsruhe in 1870-'71 was 10 days, and LOSSEN (H.) (*Kriegschirurgische Erfahrungen aus den Barackenlazarethen zu Mannheim, Heidelberg und Carlsruhe* 1870 *und* 1871, in *Deutsche Zeitschrift für Chirurgie*, Leipzig, 1872, B. I, p. 544) states that at Mannheim the mean average was 9 days.

[2] FORMENTO (F., jr.), *Notes and Observations on Army Surgery*, New Orleans, 1863, p. 57.

A first attack of erysipelas by no means secured the patient against a second, and as a rule it would seem that the later attacks were the more virulent. On page 433 of this volume has been detailed the case of Private *S. Prillaman* (CASE 674), in which the patient had nine separate attacks of erysipelas, and in the two following cases repeated attacks of the disease were noted:

CASE 1217.—Private H. B. Williams, Co. G, 27th Indiana, received a shot wound of the left wrist, at Antietam, September 17, 1862. He was admitted on the next day into hospital at Frederick. Acting Assistant Surgeon W. S. Adams reported: "Wrist joint much disorganized; ball passed through left wrist, comminuting the small bones; finger readily passes through the opening. September 20th: Extensive erysipelas from elbow to fingers; made a free incision along the arm to the wrist and two incisions along the dorsum of the hand. Ordered lead and opium wash to be freely applied and to take fifteen drops of tincture of iron every three hours, two ounces of brandy every two hours, and three grains of quinine every three hours; generous diet. In the course of three or four days the patient passed into other hands, and I saw no more of him until November 19th, when he again came under my care. He stated that he had had a second attack of erysipelas some time in October. At this date, November 19th, there is felt evidence of a third attack; pulse 120, feeble; some diarrhœa; tongue red and glassy. Iron, quinine, brandy, and generous diet ordered. November 20th: Patient worse; erysipelas has extended to face, which is much swollen; 21st, eyes nearly closed; treatment continued; affected parts kept continually wet with opium wash; 22d, swelling diminishing and parts assuming a darker hue; 24th, swelling almost entirely gone; appetite improving; brandy and quinine continued, but iron omitted on account of diarrhœa; 26th, diarrhœa checked; cod-liver oil ordered; 28th, stomach tolerated the oil; appetite improving; pulse 120, and small. December 2d: Erysipelas has again set in on the arm; lead and opium resumed; 3d, made several free incisions and evacuated considerable pus; 6th, patient has several unmanageable bed-sores, and was to-day placed on a water-bed. On December 10th diarrhœa again set in; he gradually failed, and died December 27, 1862. *Post-mortem:* On opening the chest the right lung was found to be firmly adherent to the diaphragm and pleura costalis. Its middle and upper portions were thickly studded with miliary tubercles, and the upper portion of the middle lobe was in a state of diffused suppuration. But few tubercles could be found in the left lung. On examining the arm the integument over the external condyle was found to have sloughed away and the bone was in a state of necrosis; the elbow joint contained pus; the inferior extremity of the ulna had ulcerated; the carpal bones were comminuted and carious. Carpal extremities of second, third, and fourth metacarpal bones near joints were in a necrosed condition and the joints opened. The lower extremity of the radius was comminuted: there was also union of an oblique fracture at its middle third." The bones of the right forearm and parts of the carpus and metacarpus were sent to the Army Medical Museum by Dr. Adams, and form *Specimen* 3838 of the *Surgical Section*.

CASE 1218.—Lieutenant *N. Austin*, Co. E, 14th South Carolina, aged 30 years, was wounded at Gettysburg, July 3, 1863. Acting Assistant Surgeon J. T. Laning reported: "Wounded in the upper part of the right thorax, causing a fracture in both the clavicle and scapula. Admitted into the Cavalry Corps hospital on July 14th. On the evening of July 17th the patient was taken with a chill, and on the 18th erysipelas developed itself on the right arm. Tincture of iron was applied to the part and given internally. By July 23d the arm was much swollen, discolored, and ecchymosed. On the 24th a free incision was made in the middle of the arm, from which a great quantity of very unhealthy pus was discharged. The patient was greatly prostrated, but improved quickly under tonics and generous diet. On August 5th erysipelatous inflammation set in over the right hip, accompanied with great swelling, but soon disappeared. On August 12th the disease appeared in the forearm, to which wet bandages were applied. On the 19th erysipelas manifested itself in the shoulder above the incision, and was combated with tincture of iodine and wet cloths to the parts." The patient was transferred on August 21, 1863, and paroled.

Generally the disease confined itself to the parts first infected, and thence extended in a centrifugal manner, showing that, as Socin expresses it, "the matter causing the inflammation spread itself abroad more by the way of imbibition than in the direction of the larger venous and lymphatic vessels;" however, swelling and abscesses in the axillary and inguinal regions were not infrequent. In the case of Pease (CASE 263, p. 114, *ante*) large inguinal and popliteal abscesses were noted after the attacks of the disease.

Sometimes the disease spread itself over the neighboring parts and affected nearly the whole body. Cases are on file in which the erysipelas made its appearance in the head and extended down the neck and chest to the pelvis, or in which the disease originated in a wound of the hand and spread over the arm and trunk and even the face; or where it first showed itself in the toes and attacked the leg, thigh, and lower portion of the trunk. In the case of *Walker*, cited on the opposite page, the crest of the left ilium was fractured; the disease spread from the wound first over the entire trunk, and then over the neck, thigh, and arms. In the case of Williams, 27th Indiana, cited above, erysipelas followed a shot wound of the wrist and extended to the face. Erysipelas in the upper and lower extremities seems to have been equally liable to attack the trunk.

CASE 1219.—Private Jesse Massey, Co. A, 129th Illinois, received a shot wound of the left hand, at Resaca, Georgia, May 15, 1864. The index finger was removed at the field hospital. On May 21st he was admitted into the field hospital at Bridgeport, Alabama. Soon after admission erysipelas affected the hand, the whole arm and trunk in succession. Several abscesses had to be opened. Iodine was applied externally. The patient recovered and was furloughed June 28, 1864, at which date the wound had healed; there was some contraction of the fingers, caused by erysipelas.

CASE 1220.—Private George Lincoln, 9th Illinois, aged 27 years, was wounded at Fort Donelson, February 15, 1862. A rifle ball passed from side to side through the arch of his foot, comminuting the anterior portion of the tarsus and the metatarsal bones. The patient was conveyed to the Academy Hospital at Nashville, where Dr. T. L. Madden, of Nashville, amputated the foot, after the method of Pirogoff, on February 25th. Erysipelas appeared upon the stump on March 2d, and extended thence over the greater portion of the body, causing death on March 8, 1862. The case is reported by Surgeon E. Swift, U. S. A.

CASE 1221.—Assistant Surgeon A. K. Smith, 1st Michigan Cavalry, remarks, on the monthly report of sick and wounded of the 1st Michigan Cavalry, near Fort Scott, Virginia, for January, 1863: "The case of traumatic erysipelas supervened on a gunshot wound of the foot received on January 9, 1863. The ball entered the dorsal surface between the last phalanges of the second and third toes, and passed out on the plantar surface an inch posterior to the commissure of the toes. The last phalanx of the second toe was shattered and the metatarso-phalangeal articulation opened. The case was not seen until the 14th. The wound and foot were then considerably inflamed, tense, and painful. Amputation was not then thought advisable in the then condition of the parts. Water dressings with cold irrigation were employed, but the wound did not assume a healthy appearance. The track of the ball did not slough; healthy suppuration did not take place, and there was no granulation. The wound continued to look dry, purple, tumid, and the slight discharge that took place was of a serous or semi-sanguinolent character. The general health, however, seemed good. On January 20th an erysipelatous blush first appeared around the wound, and in a few hours an erysipelatous inflammation of the cellulo-cutaneous variety was fully established, accompanied with febrile symptoms of an irritative type. The erysipelas spread rapidly up the limb until, on January 30th, it had reached the body. The limb was much swollen, tense, of a dusky red color, and covered in patches with vesicles. The foot was greatly swollen, tense, boggy to the touch, of a purplish hue, and covered with blebs. The wound was livid, dusky, emitting a sanious offensive secretion. Thus matters went on until January 25th, when there seemed to be great danger of gangrene of the wound and foot. The erysipelas was still spreading upward; the constitutional symptoms were becoming serious; the parts contiguous to the wound were dark, boggy, almost insensible, and the discharges from the wound were offensive. Amputation of the second toe at the metatarso-phalangeal articulation was resolved upon, notwithstanding the condition of the parts and the general symptoms. This was done on January 25th. Two reasons led to this course. First, it was thought the incisions would be beneficial by relieving the tension of the parts and by affording a free outlet for the secretions of the wound and the inflammatory effusion; and, second, it would remove a source of irritation in the fractured and shattered phalanx. The operation did not aggravate any of the symptoms but rather mitigated them. They remained about the same for four days, when a general amendment began, which has continued up to this time, February 5th. The inflammation of the leg has subsided, desquamation taking place. The swelling of the foot, though still considerable, is much reduced; the wound has put on a healthy character and is now secreting healthy pus and showing healthy granulations; the febrile symptoms have subsided and the patient's general condition is rapidly improving. He is convalescent. The treatment has been isolation, that the other wounded men might not be endangered, good ventilation, nutritious animal diet, muriated tincture of iron, and wine; locally a solution of lead wash to the limb and a solution of chlorinated soda to the wound."

Four hundred and fifty of the one thousand and ninety-seven cases of erysipelas proved fatal, a mortality rate of 41.0 per cent.

TABLE CLX.

Numerical Statement of One Thousand and Ninety-seven Cases of Traumatic Erysipelas, indicating the Results and Causes of Death.

In sixty cases death was ascribed to pyæmia, in eight to gangrene, in five to tetanus, in twelve to hæmorrhage, and in sixty-six to other diseases. In one hundred and sixty-eight instances only was the fatal issue directly attributed to erysipelas, making a fatality of 15.3 per cent. in the one thousand and ninety-seven cases attended by this complication.

Erysipelas made its appearance under the most favorable hygienic conditions. Surgeon D. Morgan, U. S. V., in the latter part of April and in May, 1862, reports from hospital No. 3, at Evansville, which was located on high ground, free from moisture, and with nothing to interfere on either side with the free circulation of air, that he had "no epidemic disease unless it be erysipelas which followed some of the wounds." It was observed that the disease prevailed less extensively in tents than in hospital buildings.

Generally the disease occurred in crowded hospitals with illy-ventilated rooms and rapidly spread from one wounded patient to another. This was the case in Louisville in November and December, 1862, where the progress of the affection, although quite virulent, was successfully checked by the use of bromine. In their reports Surgeons M. Goldsmith and B. Woodward, U. S. V., speak enthusiastically of this agent as a prophylactic against erysipelas. Surgeon Woodward remarks that "since the use of bromine in vapor not one case originated in the crowded wards of the barracks [Park Barracks Hospital, Louisville], in which, before its use, from five to eight cases of erysipelas a week had occurred." In the application of bromine in erysipelas two different methods were employed: first, by the action of the vapor of bromine on the affected part; second, by a direct application to the erysipelatous surfaces of a solution of bromine of varying strength. In the first method, the part affected was enveloped in dry lint; a cloth saturated with pure bromine was then applied over this, and the whole dressing covered with a piece of oiled silk. The only objection to this treatment was the tendency of the bromine to blister the skin by soaking through the intervening layer of dry lint. The other mode of using the bromine was to apply directly to the inflamed integument a solution of the bromine and bromide of potassium of the strength of from fifteen to forty drops of the former to the ounce of water.

The treatment of erysipelas with bromine was principally confined to the hospitals at Louisville, under the supervision of Medical Director M. Goldsmith. At other hospitals the patients were at once isolated, or sent to separate wards, where disinfectants were freely used. In the great majority of cases the disease yielded readily to a local application of tincture of iodine and cloths saturated with a solution of creasote, the former to the wound and inflamed surface, the latter a little more extensively to the neighboring parts. The internal treatment consisted of tincture of muriate of iron in small doses, often repeated, with quinine, etc., and good diet. In severe cases evaporating lotions of ether were applied to the worst points and numerous incisions or scarifications made to relieve the tension, as in CASE 78, page 37, *ante*.

Opinions differ greatly as to the origin and mode of infection of traumatic erysipelas. Billroth, in 1863,[1] believed that it might "result from retention of the secretion of a wound, and consequent reabsorption of a slight amount of putrid substance, in which case it is so much like lymphangitis that at the commencement it is often difficult to distinguish the two diseases. In many sporadic cases no definite cause can be found; in other cases epidemic influences seem to come into play, for at the same time a large number of wounded patients are attacked by the disease. Crowding such patients in badly-ventilated places

[1] BILLROTH (T.), *General Surgical Pathology and Therapeutics*, translated from the fourth German edition by CHARLES E. HACKLEY, New York, 1871, p. 313.

also develops a contagion, concerning which we are doubtful if it acts only on wounds, or, being taken in by the lungs, may induce erysipelas in the wound; the latter is not very probable." Socin[1] claims that the originally pure local inflammation may generate substances of a peculiar nature, which have the faculty of spreading very rapidly over the neighboring parts, causing similar inflammation, while at the same time the deleterious matter passes into the blood and produces high fever; or that the disease may be caused by the import of a specific agent—virus, if you wish it—of the nature of which we know very little; but it may be stated that "it must be of a very perambulating kind; that it does not necessarily depend on the presence of pus or infiltration; that it is by no means present in every case of pus or infiltration; that it maintains itself for a long period outside of the body without losing its efficacy, and finally that we know of no remedy which will thoroughly exterminate it." After his experience in the Franco-German War, 1870–'71, Billroth abandoned the idea of septic infection and ascribed the disease to specific contagion:[2] "Since I have conducted operations with disinfectants and the utmost cleanliness I have had no further cases of septic erysipelas, none but cases of erysipelas occasioned by contagion, and nearly all were observed in cases of wounds with healthy granulations. I now believe that I have inoculated the disease, in the patients who shortly after the operation were attacked by erysipelas, by sponges, bandages, etc. Whenever in the last few years cases of retention of decomposed blood or secretion occurred—a matter which cannot be always avoided—I noticed no erysipelas, but only a simple form of inflammation of the areolar texture. Genuine erysipelas can be carried into the wound at every stage; it has nothing to do with the reparative process of the wound, and is always an accident introduced from without. * * * That among the one hundred and thirty-two wounded treated by me at Weissenburg only one, and at Mannheim only a few isolated cases occurred, certainly proves that retention of secretion itself does not produce erysipelas. * * * Immediate isolation of the cases, as well as thorough ventilation of the barracks, prevents the further propagation of this fatal wound complication."

Very recent wounds were attacked by erysipelas, and again the disease occurred in wounds with perfectly healthy granulations, or which were well advanced in cicatrization, as in the following:

CASE 1222.—Private Arthur Farey, Co. C, 183d Pennsylvania, aged 35 years, was wounded at Cold Harbor, Virginia, June 3, 1864. He was admitted into the hospital of the First Division, Second Corps, and on June 11th was transferred to Philadelphia and entered South Street Hospital. Acting Assistant Surgeon J. A. McArthur reported: "Wounded by an explosive ball, which entered the right side of the thorax one and a half inches from the acromion. At date of admission the wound of entrance had entirely healed. The right arm was very much swollen and inflamed. A large abscess formed, situated immediately over the biceps muscle; general condition poor. On June 12th I opened the abscess and extracted the ball and ordered that the wound caused by opening the abscess be freely injected three times a day with a solution of chlorate of soda; painted the whole arm and forearm with tincture of iodine and applied a bandage. Flaxseed poultice, mixed with lead-water, to be applied to the wound. Four bottles of porter were given daily, and a mixture composed of sulphate of quinine one drachm, tincture of muriate of iron one drachm, water six ounces, and simple syrup two ounces, was given in tablespoonful doses four times a day. June 20th: The pain and swelling of the arm have almost disappeared; wound discharging healthy pus; general health good. Injections kept up and poultice and iodine discontinued. July 18th: From the last date the patient continued steadily improving till the present time. He is again suffering from erysipelas over the whole of the right arm. The wound over the biceps is very unhealthy and discharging a large quantity of sanious pus. Abdomen tympanitic, pulse fluttering, legs œdematous. July 20th: Gradually sinking, pupils very much contracted; semi-comatose; able to pass his urine and fæces properly. Died July 22, 1864, at 3 p. m. Autopsy: Brain healthy; heart contained two clots (fibrinous), one lying loose in the left ventricle and one occupying the right auricle and extending into the pulmonary artery. There was about six ounces of effusion in the pericardium. Stomach and small intestines healthy; about two quarts of effusion in the peritoneal cavity, and large depositions of lymph on various parts of the intestines. Liver cirrhosed. Upon laying open the wound made by the ball discovered that the missile had passed through the glenoid cavity of the scapula, partially fracturing the head of the humerus, and passing

[2] BILLROTH (T.), *Chirurgische Briefe aus den Kreigs-Lazarethen in Weissenburg und Mannheim* 1870, Berlin, 1872, p. 97.

around the bone lodged beneath the fascia covering the biceps muscle." The upper half of the right humerus was forwarded to the Army Medical Museum by Dr. McArthur and constitutes *Specimen* 3669 of the *Surgical Section*. There is a double longitudinal partial fracture of five inches on the inner side of the shaft. The head is carious, and necrosed bone borders the lines of separation in the shaft. A brief abstract of this case was given among the alleged instances of injuries by explosive bullets on page 702, *ante*.

CASE 1223.—Sergeant M. V. B. Carr, Co. K, 104th New York, aged 25 years, received a shot wound of the left leg, at Gettysburg, July 1, 1863, and on July 19th entered the hospital at York, Pennsylvania. A minié ball entered the outer aspect of the upper third of the left leg, passed downward and backward, and emerged on the posterior part three inches below the popliteal space. On admission the parts were swollen and the discharge of pus abundant. Simple dressings applied. On October 12th the wounds were still open; condition good. The patient was furloughed on October 28th and readmitted on December 6th. The wound of entrance became unhealthy, and on January 15, 1864, was four by two inches in extent; granulations flabby, not disposed to cicatrize, leg swollen but not painful. The parts were touched with solid nitrate of silver daily and simple cerate applied. By March 1st the wound was nearly closed though three inches deep. April 1st: Wound closed; no swelling of part, nor pain; leg lame. April 10th: Wound of entrance reopened; discharge slight. May 1st: External part of leg red, painful, and swollen for several days; abscess discharged. Wound of exit reopened May 19th; wound of exit nearly closed; leg less swollen and painful. On May 21st the patient was transferred to Ladies' Home Hospital, New York. Acting Assistant Surgeon G. M. Smith reported that "on admission the wound was healed, but the patient was quite lame. He was soon after attacked with erysipelas of the left leg. A lotion composed of three ounces of spirit of mindererus, one of alcohol, and twelve of water was applied to the limb, and muriated tincture of iron given internally. In the subsidence of the erysipelas he soon regained his general health. He was discharged from service July 28, 1864. The wound in the left leg had healed, but the limb was purple and œdematous and the patient quite lame."

Erysipelas was noted in four hundred and fifty-two cases of amputations and in one hundred and six cases of excisions. Of the four hundred and fifty-two amputation cases the disease occurred in one hundred and fifty-one instances before, and in three hundred and one after the operation. Of the one hundred and six cases of excisions the complication made its appearance in all but four cases after the operation, and here again the liability of this operation to be complicated by erysipelas will be noted.

Regarding the years in which the erysipelas was recorded, it can only be stated that the disease was most frequent in periods in which the number of wounded under treatment was the largest. Five cases were noted in 1861, one hundred and forty-three in 1862, three hundred and one in 1863, four hundred and forty-nine in 1864, one hundred and thirty-two in 1865, and in sixty-seven cases the year was not stated. The same may be said of the seasons of the year, although it was generally more frequent in cold and damp seasons and at times when it was necessary to keep the doors and windows of hospital buildings closed. Thirty-nine cases originated during January, twenty-nine in February, thirty-eight in March, seventy-seven in April, one hundred and thirty-one in May, one hundred and twenty-four in June, one hundred and seven in July, seventy in August, fifty-nine in September, fifty-seven in October, thirty-five in November, thirty-six in December, and in two hundred and ninety-five cases the month in which the disease manifested itself was not recorded.

The wounded among the colored troops seem to have been seldom affected by this disease, as only eleven were attacked by it; but five of the eleven cases proved fatal—four in consequence of erysipelas, and one of pleuritis and erysipelas.

PYÆMIA.

The terms septæmia, septicæmia, ichorrhæmia, pyæmia, pyohæmia, toxæmia, etc., found on the surgical reports of the war, were probably used by the surgeons as expressing, in their opinions, certain degrees or phases of blood poisoning, intelligible to themselves, but which the descriptions of the cases fail to reveal, and which, therefore, have not been adhered to here. Nor have the many careful investigations since the war enabled writers on surgery to reconcile the differences of their views. Lidell[1] believes that pyæmia is the

[1] LIDELL (J. A.), *On Pyæmia*, in *United States Sanitary Commission Memoirs*, New York, 1870, Surgical Volume I, page 511.

"variety of septæmia in which some local suppuration constitutes the primary focus or source of infection. In the other varieties of septic blood poisoning the source or focus from which the poison proceeds, and the symptoms, or secondary disturbances and structural lesions induced by it in distant organs, are of quite a different nature, as, for example, we may see, in cases of dissection wound, gangrene from injury of blood-vessels, senile gangrene, spreading inflammatory gangrene, and hospital gangrene." Hueter declares that the "first wound fever is essentially a septicæmic fever. * * In the course of a few days the wound fever gradually loses the character of the simple septicæmic fever, and with the appearance of suppuration changes into a septico-pyæmic fever; and, finally, with the extinction of the putrescent process and the continuance of suppuration into a simple pyæmic fever."[1] Socin claims that the various forms of the primary wound fever caused by the reception into the blood of putrid fermentative products should be designated as septicæmic fevers, and those caused by the resorption of certain pyogenic products of pus as pyæmic fevers.[2] Billroth contends that septicæmia most frequently appears in the first days after severe injuries, at a time when pus has not yet formed in the wound, and that pyæmia is found after local suppuration has been established, and adds: "I have not seen a single instance of this disease in which there was not found, either on the living subject or on the cadaver, a deposit of pus or ichor, from which it had originated."[3] A similar fact was noted by Lidell. In not one of the fifty-seven cases observed by him at the Stanton Hospital did "pyæmia make its appearance previous to the establishment of local suppuration."[4] Arnold, who cites detailed accounts of numerous *post-mortem* examinations in cases of traumatic pyæmia, discriminates between simple septicæmia and septico-pyæmia accompanied by metastatic abscesses, which latter he designates as pyæmia.[5]

The reports of the cases of blood poisoning of the American civil war are not sufficiently clear and indicative to follow the hypothetical discriminations pointed out by the authors cited, and the entire series will here be considered under pyæmia.

The total number of cases of pyæmia after shot wounds was two thousand eight hundred and eighteen (2,818), of which seventy-one (71) recovered, and two thousand seven hundred and forty-seven (2,747) terminated in death—a mortality rate of 97.4 per cent. In twenty-one (21) only of the two thousand seven hundred and forty-seven (2,747) fatal cases were other causes than pyæmia mentioned as having influenced the fatal issue, viz: hæmorrhage in seven, gangrene in six, tetanus in two, erysipelas in one, peritonitis in one, and typhoid pneumonia in four. In the remaining two thousand seven hundred and twenty-six (2,726) fatal cases death was ascribed to pyæmia.

Whether in the cases attacked by pyæmia the wounds were in the head, the face, the neck, the trunk, or the extremities; whether the injuries were only flesh wounds or accompanied by fractures; or whether they were treated conservatively or by operative interference, seemed to be immaterial; all were alike fatal, as shown in TABLE CLXI, on the opposite page.

Over one-half of all of the cases of pyæmia were found after wounds of the lower extremities; in eighty-six thousand four hundred and thirteen (86,413) injuries of this class, one thousand five hundred and sixty-four (1,564, or 18.1 per thousand) cases of

Aggregates		2,818	71	2,747	97.4

pyæmia being reported. Of eighty-seven thousand seven hundred and ninety-three (87,793) injuries of the upper extremities, nine hundred and eighteen (918, or 10.4 per thousand), of forty-five thousand one hundred and eighty-four (45,184) injuries of the trunk, two hundred and seventy (270, or 5.9 per thousand), and of twenty-six thousand four hundred (26,400) injuries of the head, face, and neck, sixty-six (66, or 2.5 per thousand), were followed by this complication.

In one thousand seven hundred and twenty-one (1,721) cases the day of the appearance of the pyæmic symptoms after the injury was noted as follows: On the

2d day in	5 cases.	12th day in	50 cases.	22d day in	55 cases.	35th to 40th day in	89 cases.
3d day in	6 cases.	13th day in	59 cases.	23d day in	42 cases.	41st to 45th day in	55 cases.
4th day in	13 cases.	14th day in	54 cases.	24th day in	40 cases.	46th to 50th day in	42 cases.
5th day in	16 cases.	15th day in	60 cases.	25th day in	42 cases.	51st to 100th day in	151 cases.
6th day in	17 cases.	16th day in	76 cases.	26th day in	50 cases.	101st to 150th day in	30 cases.
7th day in	24 cases.	17th day in	68 cases.	27th day in	31 cases.	151st to 200th day in	8 cases.
8th day in	29 cases.	18th day in	70 cases.	28th day in	36 cases.	201st to 250th day in	9 cases.
9th day in	38 cases.	19th day in	66 cases.	29th day in	31 cases.	251st to 300th day in	5 cases.
10th day in	37 cases.	20th day in	65 cases.	30th day in	20 cases.	Above 300th day in	4 cases.
11th day in	37 cases.	21st day in	56 cases.	31st to 35th day in	135 cases.	Total	1,721 cases.

From the second day after the injury the number of cases increases gradually and almost regularly until the sixteenth day, on which the highest total, viz, seventy-six, is recorded; from the seventeenth to the thirtieth day after the injury the number decreases; after that period the disease appeared at desultory intervals, in some instances as late as two hundred and three hundred days, and, in one case, a case of recovery, the pyæmic infection was ascribed to the wound over four and a half years after the injury.

In the above statement the days of appearance of the pyæmia after the injury are given; but frequently the disease was not noted until excision or amputation had been performed, and it is safe to say that in many, perhaps in the large majority of these cases, the pyæmic infection was induced or influenced by the operative interference. In TABLE CLXII, on page 860, the day of the appearance of the disease is indicated in the conservatively treated cases from the day of the injury—this includes a number of cases in which pyæmia existed at the time operative interference was decided upon; in the cases of excision and amputation, from the day of the operation. In the cases treated without operative interference the disease most frequently appeared from the tenth to the twentieth day, while in the cases of excision and amputation by far the larger number occurred from the first to the sixth or seventh day.

Table CLXII.

Indicating day of Appearance of Pyæmia after Injury and after Operation.

Day of Appearance.	In Conservative.	After Excision.	After Amputation.	Day of Appearance.	In Conservative.	After Excision.	After Amputation.	Day of Appearance.	In Conservative.	After Excision.	After Amputation.
1st	7	37	13th	28	5	18	25th	20		12

The duration of the pyæmia from the day on which the first symptoms were observed to the day of death was reported in one thousand six hundred and eighty-seven cases. The deaths occurred on the—

1st day in ..... 71 cases.
2d day in ..... 96 cases.
3d day in ..... 172 cases.
4th day in ..... 171 cases.
5th day in ..... 204 cases.
6th day in ..... 161 cases.
7th day in ..... 148 cases.
8th day in ..... 123 cases.
9th day in ..... 92 cases.
10th day in ..... 81 cases.
11th day in ..... 64 cases.
12th day in ..... 50 cases.
13th day in ..... 41 cases.
14th day in ..... 29 cases.
15th day in ..... 24 cases.
16th day in ..... 17 cases.
17th day in ..... 21 cases.
18th day in ..... 14 cases.
19th day in ..... 12 cases.
20th day in ..... 15 cases.
21st to 25th day in ..... 33 cases.
26th to 30th day in ..... 18 cases.
31st to 35th day in ..... 12 cases.
36th to 40th day in ..... 11 cases.
41st to 45th day in ..... 3 cases.
46th to 50th day in ..... 1 case.
Above 50th day in ..... 3 cases.

About two-thirds of the cases died within the first seven days; the largest number of deaths was recorded on the fifth day; in eighty-one only of the one thousand six hundred and eighty-seven cases did the patients survive the twentieth day after the appearance of the disease.

Traumatic pyæmia was seldom noticed unless the bony structure was injured. Of one hundred and sixty-five thousand eight hundred and twenty-one (165,821) wounds without lesion of the bones, only five hundred and sixty-four (564), or 3.4 per thousand, were followed by pyæmia, while of the seventy-nine thousand nine hundred and sixty-nine (79,969) shot fractures, two thousand two hundred and fifty-four (2,254), or 28.1 per thousand, were followed by this complication.

Very little is to be said of the treatment of pyæmia; tonics, stimulants, and a supporting diet were given, but, as has already been seen, with very little effect, as 97.4 per cent. of all the cases proved fatal. In the early stages of the disease sulphate of quinine in large doses would greatly reduce the temperature; but the improvement seemed to be only temporary unless the treatment was continued for some time, which, frequently, the patients were unable to bear. The disease appears to have been controlled in this manner in the following case:

Case 1224.—Private George Leigh, Co. C, 3d Artillery, aged 19 years, was wounded at Robinson's Ford, September 23, 1863, by a shell fragment which carried away a portion of the right foot. Amputation at the ankle joint was performed on the field by a modification of Syme's method. The heel being injured, the flap was taken from the dorsum of the foot. On September 25th he was admitted into Stanton Hospital, Washington. Surgeon John A. Lidell, U. S. V., reported: "His general condition was then far from satisfactory, as he was pale and very feeble. He was put upon the use of stimulants, tonics, and a good diet. Simple dressings were applied to the stump and he was directed to take an anodyne at night. September 29th: Half of

the flap sloughed off; granulations pale; discharge thin and serous; Labarraque's solution, diluted, was applied to the stump. October 11th: had a severe chill this morning, and complains of a good deal of pain in the right knee; twenty grains of sulphate of quinine and an ounce of whiskey were given every six hours. 12th: had another severe chill; knee red, hot, and very much swollen, pulse frequent and weak, tongue dry and coated, complexion assuming a bronzed hue; quinine repeated, and five grains of citrate of iron and quinine, in pill, ordered to be given night and morning. A lotion of acetate of lead and opium was applied to the knee and lime water to the stump. 13th: had another chill to-day, but it was not so severe as the others; temperature of inflamed knee lessened; had slept well during the night; no change in the treatment. 14th: swelling of the knee much less; treatment unchanged. 15th: had a slight chill about noon, but his general appearance is much better; same treatment continued. 18th: had vomiting, produced apparently by the large doses of sulphate of quinine, which were discontinued; but the other treatment was continued. 20th: bowels constipated; five grains aloes and fifteen of rhubarb were ordered. 25th: swelling disappearing from knee rapidly; stump looks much better; granulations more fluid and healthy; discharge more laudable. October 30th: decided daily improvement; continued the stimulants, together with the citrate of iron and quinine, and the lead and opium lotion to the knee and lime water to the stump. The knee joint remained slightly swollen, hot, and tender for a long time; indeed, the symptoms of inflammatory action in it did not entirely disappear till about the first of February, 1864. February 20th: the amount of mobility at the knee is small (false anchylosis); patella now adherent; knee natural in size and shape. Stump sore on account of having bruised it recently; general condition excellent. March 29th: the stump has refused to heal; there is an indolent excavated ulcer about the size of a franc piece situated at the posterior part of the face of the stump. The stump is otherwise unserviceable on account of the delicate character of its covering, which had been taken from the dorsum of the foot. There being now no prospect that it would ever become useful, the leg was reamputated about the junction of the middle with the inferior third by the double-flap method, the anterior flap being considerably shorter than the posterior one. The tibia was sawn off obliquely, as directed by Sanson; anæsthetic sulphuric ether. April 18th: patient's general condition excellent." This soldier was discharged September 17, 1864, and pensioned; he died September 13, 1871. The amputated stump was contributed to the Army Medical Museum by Dr. Lidell, and is numbered 2165 of the *Surgical Section.*

In the well established cases of pyæmia all remedies were found ineffective. In wounds of the extremities amputation has been recommended for the removal of the infection when first observed; but even this extreme remedy seemed to be of little avail. Three or four cases are reported in which limbs were removed while the patients were in a pyæmic condition, and from the successful issue it may be presumed that the removal of the infectious focus had a beneficial influence, as in the following cases, in which chills had occurred shortly before the operation:

CASE 1225.—Corporal C. Killan, Co. H, 2d Michigan, received a shot wound of the right elbow joint, at Fair Oaks, May 31, 1862. He was admitted on June 2d into hospital at Annapolis, Maryland. Surgeon T. A. McParlin, U. S. A., reported: "The ball entered close to the external condyle of the humerus, fractured the olecranon process of the ulna, and passed out just below the internal condyle of the humerus. On admission the arm was much tumefied; intense inflammation. Constant application of iced water was made to the parts for two days by means of a syphon; the inflammation having somewhat subsided, an attempt was made to save the arm by making a crucial incision and removing the olecranon process by means of a metacarpal saw. All splinters were removed and the parts brought together with sutures and adhesive straps. The joint was kept from the air by means of an albumen scab. The arm was kept at perfect rest by a splint, and water dressings used. For ten days the arm did well, when sudden tumefaction of the entire limb supervened, with intense inflammation. The dressings were removed, save such as were required to keep the wound from the air. A heavy chill with evidences of pyæmia came on. The patient was stimulated and supported by generous diet, but the evidences of inflammation were so marked that the arm was amputated at the lower third." Killan was discharged August 15, 1862, with a good stump, and pensioned.

In a case of shot wound of the knee with pyæmic symptoms, in which the lymphatic glands of the knee were greatly enlarged, amputation at the junction of the middle and lower thirds of the femur was performed and the patient recovered with a fine stump:

CASE 1226.—Private Joseph Jones, Co. K, 13th Tennessee Cavalry, aged 26 years, was wounded at Morristown, Tennessee, November 13, 1864, in the right knee. The ball entered near the upper edge of the patella, passed upward and backward, grazing the patella, and emerged two inches above the inner condyle of the femur. He was admitted on the same day into Asylum Hospital, Knoxville. The early progress of the case is not recorded. On May 10, 1865, a condition of pyæmia existed; the patient was scarcely more than skin and bone. The lymphatic glands in the groin were greatly enlarged; appetite nearly entirely gone; tongue dry, hard, and glassy; pulse about 120, weak; nausea and occasional vomiting. Knee and leg very much swollen; discharge very profuse and extremely offensive; soft structures of joint nearly entirely destroyed, articular surfaces very much corroded, and pus burrowing extensively about and below the knee. Acting Assistant Surgeon T. W. Baugh amputated the thigh, at the junction of the lower and middle thirds, by the circular operation. The case progressed nicely; a drachm of bisulphite of soda was given each day for the first five days, together with whiskey. After this the bisulphite was decreased to a half drachm, and quinine, iron, and whiskey added. The patient recovered with a beautiful stump. He was discharged from service August 22, 1865. The case is reported by Surgeon F. Meacham, U. S. V.

From the numerous autopsies reported in cases of pyæmia the following have been selected as indicating the conditions of the different organs in the fatal cases of this disease:

Condensed Summary of Forty-eight Post-

No.	Name, Injury, etc.	Lungs and Pleural Cavity.	Liver.	Kidneys.
1	Pt. J. Brown, H, 4th Mich., age 35. Wounds of back and hand.	Blood effused in tissue of lungs in spots; no abscesses; costal pleura strongly injected.	Flabby, ochre and slate colored on surface; homogeneous and spot'd on sect'n.	Healthy
2	Pt. G. H. Guernsey, E, 17th Conn., age 33. Flesh wound elbow; amputation.	A few inflamed, indurated, suppurating lobules in lower lobes of lungs.	Large, pale, clay colored, and somewhat fatty.	Healthy
3	Pt. N. Young, B, 108th N. Y. Fracture knee joint.	R't lung compressed; upper and middle lobes studded with abs.; left filled with abs.; cavity of lymph ¼ inch thick on pleura.	Large abs. in middle lobe cont. 4 oz. pus; tissues around indurated.	
4	Corp'l D. Ward, H, 13th Virginia; age 19. Fract. femur; amputation.	Lungs; lower lobe left carnified; hypostatic congestion in right; pleuritic effusion in left sac.	Enlarged, heavy, light colored, finely granulated in appearance and quite solid.	Natural in size, light in color.
5	Pt. W. Fader, A, 140th New York, age 20. Fracture sacrum.	Lungs; left, inf. lobe congested, both lobes infilt. with serum; masses of fib. matter in upper and lower lobes; right, same condition. Left, 22 oz., right, 24 oz.		Normal; rather pale. Ri't, 7 oz., left, 7 oz.
6	Pt. G. Shaumway, C, 10th New York Heavy Artillery. Cont. wound over right eye; age 28.	Some congestion both lungs; small abscesses in left; old pleuritic adhesions. Right, 22 oz., left, 14 oz.; effusion.	No apparent disease; gall perfectly black. Weight, 27 oz.	Small masses white substance in both. Weight of each, 6 oz.
7	Corp'l N. M. Hildreth, B, 94th New York, age 21. Fracture femur; amputation.	Metastatic abscesses in both lungs. Left lung weighed 1 lb. 12½ oz.	Abscess in right lobe; organ light colored, mottled, and finely congested on surface. W't, 5½ lbs.	Light colored, flexible, and easily torn; no abnormality observed. Weight of each, 7½ oz.
8	Capt. W. Bogardus, G, 86th Illinois, age 43. Wound over right sacroiliac symphysis.	Lungs congested; portion lower lobe right collapsed and carnified; metast. deposits in low. and masses of white substance in up. and low. lobes left lung. Weight, left, 18 oz. 4 dr., right, 18 oz. 3 dr.	Reddish brown externally, bile tinted on section; friable and nutmegged. Weight, 3 lbs. 14 oz. 4 dr.	Yellow tinged. Weight, left, 5 oz. 3 dr., right, 6 oz. Supra-renal capsules distended with bloody fluid.
9	Pt. E. Satterfield, F, 12th West Virginia, age 40. Fracture elbow joint; amputation arm.	Lungs flaccid and speckled; small yellow masses in left. Weight, right, 2 lbs., left, 1 lb. 10 oz.	Large, mottled externally, soft and congested; unpleasant odor. Weight, 7 lbs. 1 oz.	Mottled, flabby, light colored on section. Weight, right, 7 oz., left, 8 oz.
10	Pt. M. McColligan, C, 56th Mass., age 17. Fract. hum.; amp. at shoulder joint.	Both lungs collapsed and containing abscesses; pleural adhesions.	Normal	Healthy
11	Pt. A. H. Comins, K, 34th New York, age 25. Fract. fib.; amp. thigh; lig. femo. art. in cont.	Lungs dark colored posteriorly; numerous abscesses in discolored portions; ribs of pigmentary matter in upper lobe. Weight, r't, 10¾ oz., left, 9¼ oz.	Light reddish brown, hard, and full of blood. Weight, 78½ oz.	
12	Pt. E. Gallagher, F, 69th New York, age 37. Fract. ankle joint; amputation leg.	Right lung adherent to thorax; low. lobe of left conges., red col'd; fatty secretion with blood exuded; upper lobe dull slate col'd; copious frothy dirty-white secretion exuded.	Upper half of right lobe studded with small abscesses.	
13	Pt. J. Brown, F, 5th New York Cavalry, age 34. Fracture wrist joint; amputation forearm; reamp. arm.	Low. lobe right lung consolidated and partly hepatized; hard tubercles in apex and inferior portion third lobe; second lobe left lung consolidated, parenchyma unhealthy. Weight, right, 35½ oz., left, 25½ oz.	Thick, firm, acini well marked; nutmegged appearance; blackish color externally; no gall in bladder. W't, 63 oz.	Congested. Weight, rig't, 7 oz., left, 6 oz.
14	Pt. C. T. Munn, G, 77th New York, age 22. Fracture scapula.	Right lung adherent between lobes and to right costal pleura; organ somewhat pneumonic and infiltrated with pus; left lung healthy.	Enlarg'd, yellowish br'wn, soft, flabby, and fatty.	Reddish buff and mottled on surface; flabby and fatty.
15	Corp'l C. Putnam, E, 64th New York, age 27. Fracture left knee joint; amputat'n thigh.	Pyæmic patch in posterior lobe of left lung; lungs otherwise healthy; no pleuritic adhesions.	Normal size, yellow, granular, and brittle.	Healthy
16	Corp'l J. Crowley, A, 7th New York, age 25. Fracture knee; amputation thigh.	Lungs adherent to pleura and diaphragm, and interspersed thickly with pyæmic abscesses.	Contained several indurated spots supposed to be pyæmia.	Small and apparently softer than usual.
17	Pt. S. Hackett, F, 11th Penna. Res., age 25. Fracture tars. bones; Chopart's amput'n.	Metastatic abs. in lungs; large excavations partially occupied by dead tissue above right lung; pleuritic adhesions.	Large, heavy, and mottled; rough to the touch.	A little pale but natural
18	Pt. A. Hammond, H, 111th New York, age 47. Fracture left knee joint; amput'n thigh.	Posterior lobes of both lungs solidified and collapsed.	Softened; no abscesses	Softened; no abscesses
19	Pt. C. Rhodes, C, 2d Massachusetts Cavalry, age 20. Fracture right ulna.	Lungs filled with circumscribed abscesses; pleura covered with broken down lymph; effusion in left pleural cavity.	Congested; large abscess in superior lobe opening into peritoneal cavity.	
20	Pt. S. H. Stevenson, E, 34th Ohio, age 26. Wound of r't second finger.	Posterior lobes of lungs congested; tubercles in both, abscess in left; effusion in each pleuræ.	Much enlarged and very soft.	Normal
21	Capt. G. Reis, C, 15th Missouri, age 31. Fracture forearm; amputation arm.	Both lungs gorged with dark venous blood	Enlarged and congested	Natural size and healthy
22	Pt. J. Stuart, C, 8th Michigan, age 30. Fracture 8th rib.	Abscesses in lungs; left pneumonic and hepatized; old pleuritic adhesions in right; effusion in cavity.	Enlarged, soft, and yellow; fatty.	Enlarged; the two w'g'd 21⅛ oz. Mottled; capsule peeled readily; cortical port'n thickened; pale yellow.

mortem Examinations in Cases of Pyæmia.

No.	Spleen.	Intestines.	Joints.	Blood Vessels.	Remarks.
1	Large, 7×4, and flabby.	Healthy		No inflammation of neighboring veins observed.	Heart large and flabby. Recent pleuritis of right side; thin pseudo-membrane formed on lung, not adherent to costal pleura
2	Healthy	Slight patches of inflammation in lower part small intestine.		Axillary vein thick'd; clot partially brok'n down into puruloid matter.	Heart healthy; wound gangrenous.
3			L'ge abs. comm. with knee j't; syn. memb. soft and brok'n down by ulceration.		Cyst on right side containing 2 quarts serum, one on left containing a pint. Heart normal.
4	Dark purple, twice natural size; 2 fib. masses at mid. post. border; pus in low. border.	Several mesenteric glands enlarged; intestinal canal natural.		Veins of pia mater cov. cerebral filled with blood; white elas ic thromb. 2 in. long in ex. fem. vein.	Fibr. clot in ventr. of heart extending from auricle adh. to valve; clot in left ventr. near valve; clot 5 lines long in femoral artery; brain, slight opacity of arachnoid; some congestion. Stomach abnormally large.
5	Discolored inferiorly, and easily pulpified. Weight, 22 oz.	Discolored; odor putrefactive. Weight, 5½ lbs.			White fibrinous clots in heart. Weight, 11½ oz. Pancreas much enlarged and reddened.
6	Light colored along exterior and anterior border. W't, 1 lb.	Portions of ileum and large intestine congested; jejunum discolored.			Clots in heart; blood generally fluid; some conges. of brain; abs. between left supra renal capsule and kidney; pancreas enlarged. W't, 4 oz. Congestion of fundus of stomach.
7	Light colored, flexible, and speckled on section. Weight, 12 oz.	A few blood spots and some thinning of mucous membrane; otherwise natural. Weight, 4 lbs.		Clot in femoral artery of stump; another in femoral vein.	Clots in ventricles and auricles of heart. W't of organ, 7½ oz. Brain, clear serum in both lateral ventricles. Weight, 3 lbs. 9 oz.; pancreas normal.
8	Dark colored externally and internally. Weight, 9 oz. 4 dr.	Large intestine generally dark colored and containing patches of lymph; same in jejunum.			Heart, clots in both auricles and ventricles. Weight, 9 oz. Brain, serum in arachnoid and lateral ventricles; some congestion. W't, 3 lbs. 7 oz. Gall bladder contained 1½ oz. viscid tenacious bile; pancreas normal.
9	Large, flabby, light colored, and soft.	Jejunum tinted gray, mottled, speckled, and hyperæmic; ileum congested; large intestine dark col'd and hyperæmic.			Heart, large, flaccid, and containing clots. Weight, 1 lb. Brain, surface exsanguine, organ flabby. Serum in lateral ventricles. Weight, 3 lbs. 2 oz. Pancreas. Weight, 3 oz. Stomach large, mottled in fundus.
10	Abscesses in posterior superior surface.	Normal		Axillary vein clotted; contained pus and oil globules; no pus in femoral vein.	Large abscess in parietes of abdomen at insertion of rectus muscle.
11	Dark colored, solid, and quite full of blood. Weight, 11¼ oz.	Omentum extended ½ way to pubis. Intestines weighed 49 oz.		Fem. art. and vein diseased and eroded below lig.; vein inflamed above and cont'd purulent matter.	Heart surrounded by adipose tissue; 5 oz. fluid in pericardial sac. On opening skull large quantity of blood escaped; 2 clots adherent to bone internally; inguinal glands enlarged.
12	Natural		Right knee joint filled with apparently healthy synovia.	Apparently healthy.	Heart 5½ in. wide, 2½ in. thick, weighed 17¼ oz. Brain normal; diaphragm dull slate colored, with spots of lobular pneumonia and copious frothy secretions.
13	Dark mulberry color, and softened. W't, 11½ oz.	Inflated with gas	Pyarthrosis left elb'w joint; pus in cavity; articular surface partly denuded of cartilage.		Fibrinous clot in both sides heart; œsophagus pale and yellow; trachea purple and yellow; pancreas moderately soft; pale white color.
14	Large and flabby, containing about a doz. small puruloid foci.	Healthy		Veins of both upper extremities healthy.	Heart large and flabby; left ventricle dilated; white fibrinous clot in right ventricle and pul. art. Several abscesses in both upper extremities.
15	About the normal size, but softened.		Pus formations in r't hip joint.		Heart; large clot in r't ventricle, extended into auricle, inf. and sup. cavæ, and pulmonary art. and branches; clots in left ventricle; bladder contracted to size of walnut; abs. in thigh.
16	Enlarged, and almost of the consistence of pulp.	Seemingly healthy	Right hip joint literally filled with pus.	Veins of stump near end loaded with d'rk soft clots; higher up fill'd with pus nearly to Poupart's lig.	On section of right femur cavity found nearly filled with pus; extensive intermuscular abscess in thigh.
17	Normal in appear'ce; attached to diaph'm and containing pus.				Abscess through both hemispheres of brain; inguinal glands greatly swollen; deep abscess below popliteal space.
18	Softened; no abscesses.		3 oz. pus in right hip joint.	Left femoral vein filled with clots up to ext. iliac; fem. art. healthy.	Clots in right side of heart; medulla and cancellated structure of left, and medulla of r't femur red and disorganized; no abscesses in viscera.
19	Fairly congested	Congested; some adh. of transverse and ascending colon, and ulceration of small intestine.	Right elbow joint filled with pus; pus in right shoulder joint.		Walls of heart thin and flabby; valves like finest tissue paper; 2 oz. yellow serum in pericardium; brain soft; serum beneath dura mater and pia mater, and in lateral sinuses; abscess on back of left hand.
20	Soft and enlarged	Normal		Veins leading from forearm and hand diseased.	Pericardium distended with serum. Forearm and hand infiltrated with pus; gangrene; abscess on dorsal aspect left hand.
21	Considerably enlarg'd but without structural change.	Mucous lin'g of intestin'l can'l d'k venous col'd; ecchymoses.		Pulmonary veins filled with tough cord-like clots of fibrin.	Heart flabby and pale; right ventricle filled and soaked with blood.
22	Enlarged; more than ⅓ normal size; pale blue, and soft.				Large thrombi in right ventricle and auricle of heart; small thrombi in left side of organ.

No.	Name, Injury, etc.	Lungs and Pleural Cavity.	Liver.	Kidneys.
23	Pt. P. Ostre, H, 72d New York, age 21. Fracture ankle; amputation at knee.	Numerous small abscesses and patches of lobular pneumonia in both lungs.	Enl'g'd, pale, yellow, fatty, and softened.	No abnormal appearances.
24	Pt. J. Davis, L, 1st Michigan Cavalry, age 22. Fracture tarsus; resection.	Abscess in left lung filled with dark fetid pus; small abscess in right lung; effusion in left pleural cavity.	Enlarged and softened ...	Normal .....
25	Serg't W. Norton, I, 5th Wisconsin, age 20. Fracture neck right troch. major of femur.	Nearly whole of left lung inflamed	No abscesses; fatty	No abscesses; fatty .....
26	Pt. J. Thompson, D, 9th Virginia, age 21. Flesh wound left thigh.	Several abscesses in left lung; right lung healthy; 12 pints pus in left pleural cavity.	.....	Abscesses in both kidneys; pus in both ureters.
27	Serg't D. A. Lent, A, 6th New York Heavy Artillery, age 24. Flesh wound right leg.	Lungs congested; large abscess in upper lobe right lung filled with thick pus.	Normal	Small abscess in cortical portion of each; pus in ureters.
28	Pt. J. P. Yocum, A, 89th Illinois. Fracture left thigh; excision.	Left lung hepatized; 6 oz. pus in pleural cavity.	....	.....
29	Pt. *J. Wallace*, F, 21st Georgia, age 38. Fracture femur; excision.	Lungs adherent and studded with pyæmic patches; serous effusion in left pleural sac; pleurocollesis both sides.	Healthy but somewhat soft.	Healthy.....
30	Corp'l *A. W. Davis*, F, 14th N. C., age 24. Fracture tars. and met.; amputation leg.	Small abscesses in lower lobes both, and upper lobe right lung. Weight, right, 13½ oz., left, 11½ oz.	Normal	Healthy. Weight, right, 8½ oz., left, 7¾ oz.
31	Corp'l H. Darragh, K, 106th Penna., age 40. Fracture r't shoulder joint; excision.	Right lung adherent to walls of thorax and diaphragm; frothy fluid exuded from lobes on section; left lung healthy. Weight, right, 21 oz.; left, 11½.	Small, contracted, mottled, and convoluted; resembled brain more than liver. Weight, 51 oz.	.....
32	Pt. J. F. Bowser, B, 11th Pennsylvania, age 18. Fracture right knee joint; amputation thigh.	Lungs adherent; lower lobe, right, pneumonic and studded with hardened pyæmic patches; patches contained no pus; slight congestion left lung; effusion in right side.	Soft and fatty.....	Decidedly fatty .....
33	Pt. J. D. Crowter, D, 4th New York Heavy Artillery, age 24. Fracture right ankle joint; amputation leg.	Lungs; lower lobes carnified; adherent to surrounding tissue; large pyæmic patch in upper lobe, left; about 20 abscesses in lower lobe, right; effusion in each side of cavity.	Enlarged ⅓; in a state of fatty degeneration; gall bladder nearly empty; stricture near middle.	Apparently healthy.....
34	Pt. C. Smith, B, 7th Maryland, age 21. Fracture left fibula.	Lungs; lower lobes hepatized and dotted with pyæmic patches; recent adhesions about right; 20 oz. effusion.	Somewhat fatty	Somewhat fatty .....
35	Pt. C. W. Allen, C, 1st Maine H. A., age 23. Fracture left elbow; amputation arm.	Lungs slightly adherent to thorax; right lung considerably congested and containing a small abscess. Weight, right, 11½ oz., left, 9½ oz.	Abscess in right lobe filled with creamy pus. W't, 59 oz.	Apparently healthy.....
36	Pt. J. Hiles, I, 1st Nebraska, age 20. Fracture left radius; amputation arm.	Lungs; lower lobes studded with metastatic abscesses; recent deposit of lymph on both pleural surfaces.	No abscesses in liver.....	No abscesses in kidneys...
37	Pt. F. Guthberlet, K, 27th Massachusetts, age 26. Fracture right elbow; exc.; amp. arm.	Pyæmic abscesses in lungs; left collapsed; both congested and adherent to pleura.	Decomposed abscess in left lobe size of a small shot.	....
38	Pt. P. Scanlan, G, 69th New York, age 34. Fracture knee joint; amputation thigh.	Lungs, strongly marked carbonaceous deposit on; lower and posterior parts engorged; right congested and containing abscesses; pleuritic adhesions on left side.	Enlarged, adherent to diaphragm, stomach, and transv'se colon; abs. in r't lobe and on up. and r't side.	Enlarged, pale, and indurated.
39	Pt. G. Laforce, E, 26th New York. Wounds arm and knee joint; amputation arm.	Lungs black, mottled, and reticulated; melanic deposit.	Large and finely mottled..	Large and pale.....
40	Pt. J. Moore, E, 8th Pennsylvania Reserves, age 20. Fracture leg; amputation.	Lungs slightly congested; melanic matter present; abscesses in both. Weight, left, 22½ oz., right, 15½ oz.	Light coffee colored, finely mottled, and large. W't, 82½ oz.	Kidneys. Right weighed 6 oz., left, 6½ oz. Suprarenal capsules much enlarged. W't, both, ¾ oz.
41	Pt. S. McCan. F, 1st U. S. Cavalry, age 23. Fracture right ulna.	Lungs congested and coated with broken down lymph; right filled with small abscesses; effusion in left pleural cavity; each weighed 25 oz.	Three abscesses in, containing 2 oz. pus each. Weight, 5 lbs. 2 oz.	Congested. Weighed 6 oz.
42	Pt. C. Crealman, H, 118th Pennsylvania, age 21. Fracture right humerus.	Lungs contained numerous abscesses; both partially adherent and hepatized; pleura broken down and adherent to lungs; effusion in cavity. Right weighed 25½ oz., left 19 oz.	Enormously enlarged, and containing numerous abscesses.	Both contained abscesses; cortical substance congested; left enlarged; right weighed 7½, left 9 oz.
43	Corp'l J. H. Higley, A, 96th Pennsylvania, age 20. Fracture upper third femur.	Lungs congested; recent indurations as large as an egg in middle part of both near base; not converted into pus.	Nutmeg appearance on section; no abscesses in.	Contained no abscesses....
44	Pt. J. Merrow, D, 12th Massachusetts, age 31. Fracture knee joint; amputation thigh.	Two abcesses, size grain of maize, in apex left lung; surroundings of abscesses for about ½ inch of a dark pink color and denser than surrounding tissue.	Healthy.....	Pale, firm; cortical substance same hue as pyramidal.
45	Pt. J. Somers, E, 64th New York, age 21. Fracture knee joint; amputation thigh.	Abscesses in both lungs; left compressed, adherent, and carnified; right pneumonic; copious effusion in pleural cavities.	Normal	Normal .....
46	Pt. M. Casey, K, 7th Veteran Reserve Corps, age 25. Fracture right carpus.	Pyæmic patches in lower lobes of lungs; large abscess in posterior lobe of right; slight adhesions; no effusion in cavities.	Healthy.....	Pale, otherwise healthy...
47	Pt. G. McCoy, E, 62d Pennsylvania, age 32. Fracture foot; amputation leg.	Abscesses in both lungs.....	In a state of acute hepatitis and quite friable.	....
48	Pt. W. Ramsey, H, 6th Virginia, age 19.	Lungs slightly congested at posterior lobes; small pyæmic patch in right inferior lobe of right.	Normal	In a state of putrid decomposition.

No.	Spleen.	Intestines.	Joints.	Blood Vessels.	Remarks.
23	Not enlarged; paler than natural, and softened.	.....	.....	Thrombus of superf. fem., profunda, and external iliac veins.	Large thrombus in right ventricle and auricle of heart; small ones in left. Muscles of thigh infiltrated with pus.
24	Enlarged and softened.	.....	Pus in ankle joint; also in astragalo-scaphoid articulation.	Femoral vein thrombosed.	Clots in both ventricles of heart; cancellous structure of calcaneum gangrenous; osteomyelitis.
25	Not enlarged or softened.	.....	Hip joint and parts infiltrated with a dark thin fetid pus.	.....	No chills occurred although the disease lasted 42 days.
26	Large abscess in; discharging pus into abdomen; organ enlarged.	.....	Left knee and wrist joints examined; no pus.	Veins as far as examined healthy.	Heart healthy; 3 oz. serum in pericardium. Abscesses in and pus at points of right cerebrum. Pus burrowed among muscles of thigh from knee to hip.
27	Normal	Normal	Pus in right knee and wrist joints; none in ankle.	.....	Heart; right ventricle filled with a semi organized clot. Pancreas and stomach normal.
28	.....	.....	.....	.....	Parotid gland enormously enlarged and distended with pus; cartilaginous but no ossific union of fracture.
29	Enlarged but not softened.	Healthy.....	.....	Old, partially disintegrated blood clots in fem. vein; walls of vein thickened; femoral art. healthy.	Heart healthy; brain, large amount of serous subarachnoid effusion. Lymphatic glands, left groin, enlarged.
30	Soft and pulpy. W't, 12½ oz.	Cæcum congested; otherwise healthy.	.....	.....	Small clot in right side heart. W't, 9½ oz.; tissues of stump in sloughing condition; structures of bones full of oil globules.
31	Much enlarged, firm, not pulpy. Weight, 9 oz.	.....	.....	.....	Heart; fibrinous clot in both ventricles. W't, 9 oz. Arm and wound gangrenous.
32	Softer than usual.....	.....	Contained no pus.....	Femoral vein inflam'd and filled with dark clots; art. healthy.	Marrow of femur red and soft; in portion gangrenous, and entirely gone for 3 inches in lower end.
33	Considerably softened, and dark colored.	Apparently healthy..	Knee joint not involved.	Pus in one of the veins; clots in the others.	Abscesses between muscles of stump; 2 small ones near bone.
34	Healthy.....	.....	.....	Dark clot partly filled femoral vein; inside coat of vein red and inflamed; post. tib. art. oblite'd in w'd.	Large fibrinous clot in left auricle and ventricle, and long thin clot in right auricle extending into pulmonary artery.
35	Apparently healthy. Weight, 9 oz.	Apparently healthy ..	Fluid resembling pus in left shoulder joint.	Arteries and veins of stump healthy.	Large fibrinous clot in right side heart; extremity of median nerve bulbous; small abscess throughout tissues of stump to shoulder joint.
36	No abscesses in spleen	.....	No pus in joints.....	Closure of vein about 1½ inches from extremity of bone.	Fungous mushroom protrusion of medulla and other marks of osteomyelitis.
37	A grumous dark purple mass; very soft; complet'ly disorg'd.	Normal	Large abscess in shoulder joint; pus healthy.	Ves'ls of arm normal; firm black clot filled axill'y vein; no pus.	Heart normal; stump œdematous and filled with serum; bone semi-purulent throughout.
38	Enlarged, softened, dark purple, and adherent to diaphragm and peritoneum.	Transverse and descending colon and rectum reduced in calibre.	.....	Vessels of dura mater congested.	Heart livid in color and flabby; clots in right and left ventricles; dura mater tense; coats of stomach pale, soft, and injected in spots.
39	Enlarged, hard, and very light colored.	Full of gas; colon especially distended	Fibrinous, flaky, tenacious pus to hip j't; abscesses extended to knee j't; cartilages of knee j't erod'd.	.....	Bronchial glands enlarged and as black as ink; gall bladder light colored.
40	Weighed 4½ oz.....	Inflated, mottled, and streaked.	Pus in left knee joint; synovial membrane destroyed; cartilage eroded; pus in r't sh. j't; none in hip j'ts.	Phlebitis with total disorganization of fem. vein; bel. knee vein occupied by tubo filled with pus.	Brain; effusion of serum into lateral ventricles; large abscess with black walls about middle third femur; medulla of tibia softened.
41	Much congested. Weighed 10 oz.	.....	Carpus filled with pus.	.....	Heart healthy. Weighed 7 oz.
42	Soft, and of dark brown hue. W'd 8 oz.	Small intestines somewhat congested; cæcum sphacelous throughout.	.....	Vessels of fractured arm healthy.	Clot in left, and abscesses in r't ventricle of heart; trach. and bron. tubes congested; cardiac orifice of stomach congested; pancreas broken down and softened.
43	Many small abscesses in spleen; not much enlargement.	.....	.....	Thrombi in smaller veins from side nearest broken bone extend into fem. vein.	Abscess below knee broke, discharging offensive matter.
44	Dark purple color, faintly granulated; not very firm.	Healthy.....	.....	Femoral vein filled with a grayish black clot; artery filled with partially decomposed clot.	Medullary subst. yellowish, ochre-colored, and protruding from femur; no inflammation in thigh, or any of the organs; muscles attached to femur healthy; periosteum firmly adherent.
45	About the usual size and consistence.	Normal	.....	Femoral vein filled with partially softened clots nearly to Poupart's ligament.	Entire exterior of femur in a gangrenous condition.
46	Healthy.....	.....	Formation of pus in left shoulder joint.	No clots discovered ..	Soft parts of forearm, except vessels, thoroughly disorganized.
47	.....	.....	No pus in the joints	Suppurative inflammation of veins of leg.	Pericardium filled with serum; 2 oz. serum in lateral ventricles of brain; no pus, but an unusual amount of serum in all the serous cavities.
48	Decidedly softened ..	.....	.....	Thick creamy pus from face of stump to Poupart's ligament in fem. vein.	Fibrinous clot in right ventricle of heart; pyramidal bodies becoming invisible.

Abstracts of forty-eight *post-mortem* examinations are recorded in the preceding table. Metastatic abscesses were found in the lungs in thirty-five, in the liver in nine, in the kidneys in three, in the spleen in four instances, and in sixteen cases pus was found in the joints. The lymphatic glands of the groin were swollen in three cases, and in a case of a fracture of the femur (No. 28, p. 864), the parotid gland was enormously enlarged and distended with pus. Several other instances of swelling of the parotid glands were recorded in cases in which no autopsies were made:

CASE 1227.—Private Henry M. Smith, Co. G, 82d Pennsylvania, aged 28 years, received at Amelia Springs, Virginia, April 6, 1865, a compound comminuted fracture of the right knee. His right thigh was amputated in the middle third, by lateral flaps, April 6th. He was admitted to division No. 1, Annapolis General Hospital, April 15th, from City Point. When first seen, on April 28th, by Surgeon B. A. Vanderkieft, U. S. V., who reports the case, the patient was in a state of great debility, with delirium and other symptoms of pyæmia. The stump was in a very unhealthy condition, the discharge of pus sanious, and the end of the femur protruding an inch. The stump was kept clean by the use of soap and water, and oakum dressings were applied. Tonics and stimulants were administered internally. On May 2d the pyæmic symptoms were still more fully developed, the skin having assumed a yellow hue. The right parotid gland was swollen, and its external appearance indicated that an abscess had formed. The patient now lay in a lethargic state, the discharges from the bowels became involuntary, and he gradually sank. He died May 7, 1865. No *post-mortem* examination was made.

CASE 1228.—Corporal *Robert A. Wheedon*, Co. K, 47th North Carolina, aged 24 years, received a compound comminuted fracture of the right thigh, at the battle of Gettysburg, July 3, 1863. Amputation was performed in the hospital of the 2d division, First Corps, July 7th, at the upper third of the thigh. On July 12th secondary hæmorrhage occurred, supposed to proceed from a large muscular branch; was arrested, after about four ounces of blood had been lost, by elevating the stump and making pressure over the femoral artery. Pyæmia was recognized July 16th. An abscess developed in the region of the left parotid gland, which was incised July 21st, when a slight discharge of pus oozed from the incision. Quinine, stimulants, and nourishing diet were employed. The patient died July 23, 1863. No *post-mortem* examination was made. The case is reported by Surgeon W. B. Chambers, 97th New York.

CASE 1229.—Private John Kreps, Co. C, 29th Iowa, aged 16 years, received on April 30, 1864, a shot wound of the right thigh; the femur was fractured at the junction of the lower with the middle thirds, and the bone was splintered to the knee joint. He was admitted to hospital at Little Rock, Arkansas, on May 3d. The ends of the bone at the point of fracture became carious, and on July 9th amputation was performed at the junction of the upper and middle thirds of the thigh by the antero-posterior flap method; there was little hæmorrhage; chloroform was used. The patient did well till the 20th day, when abscesses formed in the stump and in the parotid gland. The patient died of pyæmia August 8, 1864. No autopsy was held. The case is reported by Assistant Surgeon E. A. Clark, U. S. V., who performed the amputation.

CASE 1230.—Private J. F. Smith, Co. C, 61st New York, aged 17 years, received, at Burksville, Virginia, April 8, 1865, a shot fracture of the right knee. On the following day (April 9th) amputation through the lower third of the thigh was performed. He was treated in field hospital, and subsequently, on May 14th, he was admitted to Armory Square Hospital at Washington. The symptoms of the case are briefly noted on the bed-card by Acting Assistant Surgeon C. H. Brown: Metastatic abscesses of surface; swelling of joints; icteric tinge of skin and conjunctiva of eye; swelling of submaxillary, sublingual, and parotid glands; joints painful? chills, and change of chill to that of burning heat; profuse diarrhœa; nausea, headache, and delirium. Death on May 24, 1865, of pyæmia and exhaustion. No autopsy was made.

CONCLUDING OBSERVATIONS ON SHOT WOUNDS.

The details of the treatment of special shot injuries and of the most serious complications have been fully described under the proper headings in this and the preceding volumes, and it is, therefore, only necessary here to allude briefly to the immediate care of the wounded after battles and engagements, and to a few points of a general character applicable to shot wounds.

Slight wounds were examined and dressed at the primary stations; those of greater severity received such care as their condition demanded, and were at once sent by the ambulance wagons to the field hospitals. The importance of an early and complete examination of the wounded seems to have been fully realized by the surgical staff. This examination was generally conducted under the influence of anæsthetics for the purpose of accurate diagnosis; in its course, balls and foreign bodies were extracted, bleeding vessels secured, and splinters of bone removed; upon its conclusion such operations were performed as in the judgment of the surgeon were necessary. In determining the extent of injury it was not unusual to enlarge the wound caused by the missile, especially in cases where the

advent of swelling caused difficulty or uncertainty of touch, or where it became necessary to remove splinters or foreign bodies. In the examination of a wound experience confirmed the common view that the finger is the surest and most intelligent probe. With regard to the removal of splintered bone and foreign bodies, experience seems to warrant all reasonable means for their removal, since they are liable to become sources of irritation and danger. The ends of splinters of bone still attached may be cut off, but forcible detachment must be avoided. Missiles should be extracted if they can be readily found and it can be done without risk to vital parts; but it should also be borne in mind that they may become encysted, giving no further trouble.

The primary dressing of wounds and operations was always of the simplest character; a piece of lint or linen held in place by the turns of a roller bandage and kept well moistened with water. Instances have been cited of great inconvenience and even of serious complications, such as gangrene and tetanus, being caused by tight bandaging. The presence of maggots in wounds, in the field and camp hospitals, was frequently an annoying complication. After protracted battles, such as the fighting on the Peninsula in June and July, 1862, and after the Wilderness and Spottsylvania, in 1864, when the means of transportation were not sufficient to move the wounded rapidly to permanent hospitals, and when the number of attendants was entirely inadequate to the demand, maggots were found in abundance in and beneath the dressings and in the wounds. Surgeon D. Prince, U. S. V., cautions "against the use of too much dressing, as the impression that the work of flies will be frustrated thereby is erroneous. While the dressings are wet flies will deposit their eggs through several thicknesses of muslin, and also along the border of the dressings, and once hatched the little ravenous maggots will insinuate themselves among all the layers of dressings and under them into the wound itself. Nothing but frequent dressing will keep them from developing in the wound. Oil of turpentine and infusions of tobacco were used to kill these pests. Petroleum or kerosene oil was tried in some cases with markedly good effect, but the most effectual remedy was a thorough examination of the dressing every two or three hours." In well established general hospitals the presence of maggots was rarely noted.

Climatic, Hygienic, and Moral Influences.—Of the effects of climate on the treatment and result of wounds the reports of the war afford but little information. Casual remarks were occasionally made by medical officers that in certain climates and localities wounds "did well," or otherwise; but so vague a statement proves of little value, as it is more than probable that insufficient consideration was given to other closely related conditions which may have exerted a stronger influence than climate itself. The change of climatic conditions experienced by our armies during the operations of the war in a sudden transition from the cool and more healthy regions of the north to the warm semi-tropical and malarious climates of the south could not fail to make itself felt on the general organism, aside from any of the concurrent exposures, hardships, or privations incident to the soldier's life. To what extent the health, vigor, and efficiency of the troops campaigning in the southern regions was impaired by causes due to climatic origin is shown in the medical portion of this work. Suffice it to say that under these acquired conditions wounds and surgical diseases suffered a corresponding modification. Laying aside the consideration of other factors, it seems that continuous dry heat is not unfavorable to the satisfactory progress of gunshot wounds; the same may be said of the same quality of cold—both probably

act as tonics to the system at large. Moist climates with continuous heat are relaxing and weakening, rendering the body less capable of resisting the onset of prevailing diseases, and cannot be considered advantageous. It has been claimed, however, that the moist climate of parts of the southern seacoast was exceedingly favorable to the healing process of wounds; it may be that the especial qualities of sea air afforded a desirable element. The pure bracing air of the highlands of Virginia, Tennessee, and Georgia were, without doubt, especially favorable to the recovery of the wounded. The successful results of wounds and operations in General Sherman's campaign from Atlanta to the sea was especially marked, though it must be admitted that very important factors other than that of mild equable climate had their full influence upon the men of that command. Sudden and extreme variations of temperature and humidity were decidedly prejudicial to the course of wounds, and seem especially to favor the access of tetanus. Prolonged cold and moisture were generally regarded unfavorably as favoring the presence of surgical complications, as erysipelas and gangrene, though here the probable explanation is that these diseases were engendered by the want of free ventilation.

The subject may be briefly summed up in the statement that those conditions of climate, wherever found, which allow the fullest and freest exposure to pure fresh air, are undoubtedly those most favorable to the rapid and uncomplicated recovery from wounds, while such conditions as tend to prevent a free out of door life, or compel the exclusion of large quantities of free air from the wards of hospitals and from barracks and tents, or such as favor the rapid decomposition of vegetable and animal matter, are to be considered as more or less prejudicial and harmful to the course and treatment of wounds.

The influences of hygienic conditions, food, and concurrent diseases, upon the results of shot injuries in time of war are similar to those observed in cases treated in time of peace in civil hospitals. The influence of the mental condition on the results of wounds is undeniable. All reports agree that the wounded of victorious troops, elated by the successes achieved by their own bravery and that of their comrades, did better than those of defeated armies. The most striking example of this influence of the mental condition on the successful treatment of wounds in modern times is the fearful mortality among the French, after shot wounds of all kinds, in the war of 1870–'71. The excessive mortality of that campaign, repeatedly pointed out in the chapters on special wounds, was undoubtedly largely owing to the mental depression caused by a succession of reverses rarely met with in the history of warfare.

Multiple Wounds.—There is no doubt that in a large proportion of the killed on the battle-field death was caused by several wounds simultaneously received; but many cases of recovery after multiple wounds have also been recorded. It is impossible to give even an approximate estimate of the frequency of the cases in which several wounds were found in the same individual. The cases were classed with those injuries which seemed to be the gravest. In the following instance there were no less than twenty-six wounds of entrance and exit. The patient died twenty-eight days after the receipt of the injuries:

CASE 1231.—Private Franz Metzel, Co. A, 11th Massachusetts, aged 31 years, was wounded at Spottsylvania, May 12, 1864. On May 25th he was admitted into Armory Square Hospital, Washington. Surgeon D. W. Bliss, U. S. V., reported: "This soldier accidentally got between or in the range of cross-firing and received twenty-six separate wounds of entrance and exit, and when admitted was sufficiently strong to converse and relate his sad fate. The wounds were by minié balls, as follows: 1st entered just anterior to external malleolus of left ankle and emerged about the middle of the sole of the foot; 2d entered left leg just above external malleolus, passed upward, and emerged five inches above the heel; 3d ball entered left leg six inches above external malleolus, and made its exit on the inner side four inches below the knee joint; 4th entered just below the head of the left fibula, and emerged on the internal aspect nearly opposite point of entrance; 5th entered left thigh exter-

nally, three inches above knee, and emerged on inner side opposite point of entrance; 6th entered left thigh on the external and middle part, passed through, and emerged opposite point of entrance; 7th entered just above the coccyx and remains in parts unknown; 8th entered the back three inches above left hip, and remains; 9th entered just below inferior angle of left scapula and remains in parts unknown; 10th, left arm, two wounds below and three above the elbow, the bones above and below being fractured; 11th entered right leg above the middle and made its exit on the calf opposite point of entrance; 12th entered about three inches below the right knee, a little internal, and remains; 13th entered right thigh externally, about the middle, and made its exit on the inner side opposite point of entrance; 14th entered upper third of right thigh, on the external side, and remains in parts unknown. He died May 30, 1864."

In the following case the patient made a good recovery after receiving four shot wounds, three of which were of a serious nature:

CASE 1232.—Private Charles Sebring, Co. F, 48th Indiana, was wounded at Iuka, Mississippi, September 19, 1862, and admitted into hospital at Jackson, Tennessee, September 19th. Assistant Surgeon J. P. Wright, U. S. A., reported: "He was first disabled by a musket ball, which passed through the hamstring muscles of the left thigh; and in this helpless condition, stricken down in the thickest of the fight, he received three other wounds from musket balls—one ball impinging upon the left parietal bone and furrowing the scalp without causing fracture; another passing through the left forearm, in its lower third, fracturing and comminuting both bones; and a third passing through the middle third of the right arm and emerging on the posterior and inner aspect, causing a comminuted fracture of the humerus. The flesh wound in the thigh healed rapidly; the wound in the left forearm continued to discharge for four months, and, after the removal of several fragments of bone, ultimately healed with loss of pronation and supination, and with contraction of the flexor tendons; it seemed, however, to cause little constitutional disturbance. The fracture of the left humerus gave to the case its peculiar interest. In November, 1862, when the case first came under my own supervision, the arm was much swelled and very intolerant of manipulation; there had been no attempt at bony union, and the exsanguineous and emaciated condition of the patient augured a speedy and fatal issue. There was a profuse discharge from both orifices of the wound, the character of which, however, was healthy; light dressings were applied and a nourishing diet enjoined. Two weeks later the limb was seized with phlegmonous erysipelas; the pain was excessive and the swelling so great that the tense and glistening integument threatened to burst. Great constitutional disturbance ensued; the stomach rejected everything that was offered, colliquative diarrhœa supervened, a harassing cough racked the patient's frame, already reduced to a skeleton by months of suffering and exhaustive suppuration, the conjunctiva became icteroid, and profuse sweats by day and night gave additional evidence of the great prostration of the vital powers. No pus was detected in the alvine evacuations; but it was strongly suspected in the sputa, and indicated by every test attainable. The local treatment adopted was scarification of the affected part, followed by warm fomentations of infusion of elm and laudanum, in which the whole limb was enveloped. The constitutional treatment was mainly supporting. About four days from its inception the erysipelatous action showed signs of abatement, attended with marked improvement of the constitutional symptoms. This favorable change continued for about three weeks, and the improved appetite and cessation of diarrhœa and exhaustive sweats again afforded encouragement. But the condition of the arm was not promising; the discharge had become very fetid, and the tissues, to the fingers' ends, infiltrated with serum. With the limb in this condition, the most favorable result to be anticipated from a second attack of erysipelas would be gangrene of the extremity; and yet, although about this period the morbid action returned, scarcely less threatening in character than before, it yielded promptly to free scarification followed by warm formentations, the only inconvenience resulting therefrom being a considerable amount of sloughing of the integument. On the subsidence of this second attack the utter prostration of the vital powers seemed almost to preclude the hope of recovery. A stimulating and nourishing diet was enjoined, ale or milk punch, according to the patient's wish, being administered several times daily, together with compound tincture cinchona, which was exhibited continuously for many weeks. From this period convalescence began." Sebring was discharged from service April 8, 1863, and pensioned. In May, 1863, his left arm was amputated near the shoulder,[1] at his home, by Drs. Grimes and Badger. He was last paid in September, 1881.

CONSERVATION, EXCISION, AMPUTATION.

The shot wounds of the extremities number one hundred and seventy-four thousand two hundred and six (174,206), or over two-thirds of the total number of shot injuries. Of these, one hundred and forty thousand one hundred and twenty-four (140,124) were treated without operative interference, four thousand six hundred and fifty-six (4,656) were followed by excision, and twenty-nine thousand four hundred and twenty-six (29,426) by amputation. To the cases of amputation should be added three hundred and five (305) amputations following excisions, and two hundred and forty-nine (249) re-amputations,[2] making the total number of amputations twenty-nine thousand nine hundred and eighty (29,980). The tables on the next two pages contain numerical summaries of the shot fractures of the

[1] See TABLE LXXXIV, No. 104, page 778, *Second Surgical Volume.*

[2] In the Surgical portion of this work the extremities have been subdivided as follows: Upper Extremities—hand, wrist, forearm, elbow joint, shaft of humerus, and shoulder joint; and Lower Extremities—foot, ankle joint, leg, knee joint, thigh, and hip joint. Under re-amputations, here referred to, are understood cases in which, for instance, the original amputation was in the leg and the subsequent operation at the knee joint, thigh, or hip joint. It was impossible to indicate in this TABLE the cases of re-amputations in the same subdivisions; as, for instance, amputations in the lower third of the thigh, with re-amputation in the middle or upper; and likewise in the leg and arm and forearm, although a great number of such instances are reported.

upper and lower extremities, indicating the seat of injury, mode of treatment, and terminations of cases.

Eighty-seven thousand seven hundred and ninety-three (87,793), with eighty thousand and ninety (80,090) recoveries, five thousand six hundred and eight (5,608) deaths, and two thousand and ninety-five (2,095) unknown results (a mortality rate of 6.5 per cent.), were shot injuries of the upper extremities. Of these, thirty-two thousand nine hundred and ninety-two (32,992) were wounds complicated by fracture, and fifty-four thousand eight hundred and one (54,801) were flesh wounds; of the latter, eighty-two (82) were followed by amputation. Of the thirty-two thousand nine hundred and ninety-two (32,992) shot fractures of the upper extremities, three thousand eight hundred and forty-one (3,841), or 11.6 per cent., were followed by excision, fifteen thousand seven hundred and thirty-seven (15,737), or 47.7 per cent., by amputation, and thirteen thousand four hundred and fourteen (13,414), or 40.7 per cent., were treated without operative interference beyond the removal of bone splinters, of missiles, or other foreign substances.

Eighty-six thousand four hundred and thirteen (86,413) were shot injuries of the lower extremities; the results were not ascertained in nine hundred and thirty-five (935) cases; seventy-three thousand six hundred and sixty-five (73,665) resulted in recovery, and eleven thousand eight hundred and thirteen (11,813) in death—a fatality rate of 13.8 per cent. Fifty-nine thousand one hundred and thirty-nine (59,139) were flesh wounds, of which two hundred and one (201) were followed by amputation. Twenty-seven thousand two hundred and seventy-four (27,274) were shot injuries involving the bones of the lower extremities; of these, eight hundred and fifteen (815), or 3.0 per cent., were treated by excision, thirteen thousand four hundred and six (13,406), or 49.1 per cent., by amputation, and thirteen thousand and fifty-three (13,053), or 47.9 per cent., without operative interference. In reality the percentage of cases treated by amputation in the upper as well as in the lower extremities was somewhat larger than here stated, as in three hundred and five (305) instances (two hundred and twenty-six in the upper extremities, ninety-two in the lower extremities) the excisions were subsequently followed by amputations, as is indicated in the tabular statements on the two preceding pages.

In the upper extremities 11.6 per cent. of the total fractures were treated by excision; in the lower extremities only 3.0 per cent. There is little difference in the relative percentage of amputation in the upper and lower extremities (in the first 47.7, in the second 49.1 per cent.); the proportion of cases of conservative treatment in the lower extremities exceeded that in the upper 7.2 per cent., being 47.9 in the former and 40.7 per cent. in the latter. It is difficult to account for this larger percentage in the attempts at conservation in shot fracture of the lower extremities, unless it be due to the instructions given during the progress of the war by medical directors of the armies that amputations in the thigh should not be performed on the battle-field, and that by the time such patients reached general hospitals the favorable time for operative interference had passed.

It is a curious anomaly that in the upper extremity conservatism was more extensively employed in the part most distant from the trunk, while in the lower extremity the reverse was the case. Of eight thousand two hundred and forty-five (8,245) shot fractures of the humerus, two thousand nine hundred and sixty (2,960), or 35.9 per cent., and of five thousand one hundred and ninety-four (5,194) shot fractures of the bones of the forearm, two thousand nine hundred and seventy-one (2,971), or 57.2 per cent., were treated by conservative measures throughout. In the lower extremities the percentage of cases of fracture

of the femur treated conservatively exceeded that of the fractures of the bones of the leg; in the former three thousand six hundred and twenty (3,620) out of six thousand seven hundred and thirty-eight (6,738), or 53.7 per cent., being treated without operative interference, in the latter four thousand one hundred and sixteen (4,116) out of nine thousand one hundred and seventy-one (9,171), or 44.8 per cent.[1]

One hundred and thirteen thousand nine hundred and forty (113,940) shot flesh wounds of the extremities, including cases of injuries of arteries and nerves in which no lesions of bone were reported, gave four thousand five hundred and sixty (4,560) fatal results, a mortality rate of 4.0 per cent., of which fifty-four thousand eight hundred and one (54,801) of the upper extremities, with one thousand six hundred and forty (1,640) deaths, gave a mortality rate of 2.9 per cent., and fifty-nine thousand one hundred and thirty-nine (59,139) of the lower extremities, with two thousand nine hundred and twenty (2,920) deaths, a fatality rate of 4.9 per cent. Of the former in eighty-two (82), and of the latter in two hundred and one (201) cases, amputation was resorted to, generally on account of hæmorrhage, aneurisms, or extended sloughing or suppuration; less frequently on account of pyæmia, gangrene, and erysipelas, and, in a few instances, on account of lacerations of nerves.

Sixty thousand two hundred and sixty-six (60,266) of the one hundred and seventy-four thousand two hundred and six (174,206) shot wounds of the extremities were complicated by injuries of the bony structure. Forty-four thousand three hundred and seventy-five (44,375) recovered, twelve thousand eight hundred and sixty-one (12,861) proved fatal, and the result in three thousand and thirty (3,030) cases was not recorded, a mortality rate of 22.4 per cent. Thirty-two thousand nine hundred and ninety-two (32,992) were fractures in the upper, and twenty-seven thousand two hundred and seventy-four (27,274) in the lower extremities:

TABLE CLXV.

Summary of Sixty Thousand Two Hundred and Sixty-six Shot Fractures of the Extremities, showing Treatment and Results.

MODE OF TREATMENT.	Cases.	Recovery.	Fatal.	Undetermined.	Percentage of Fatality.	Upper Extremities.				Lower Extremities.			
						Recovery.	Fatal.	Undetermined.	Percent. of Fatality.	Recovery.	Fatal.	Undetermined.	Percent. of Fatality.
Conservation	26,467	20,854	4,562	1,051	17.9	11,646	1,288	480	9.9	9,208	3,274	571	26.2
Excision	4,656	3,183	1,213	260	27.5	2,744	858	239	23.8	439	355	21	44.7
Amputation	29,143	20,338	7,086	1,719	25.8	12,539	1,822	1,376	12.6	7,799	5,264	343	40.2
Aggregates	60,266	44,375	12,861	3,030	22.4	26,929	3,968	2,095	12.8	17,446	8,893	935	33.7

Twenty-six thousand four hundred and sixty-seven (26,467), or 43.9 per cent., were treated conservatively; four thousand six hundred and fifty-six (4,656), or 7.7 per cent., were followed by excision; and twenty-nine thousand one hundred and forty-three (29,143), or 48.4 per cent., were followed by amputation. Of the conservatively treated cases, 17.9 per cent. proved fatal; of those followed by excision 27.5 per cent., and of those by ampu-

[1] It might be claimed, in a comparison of this nature, that the cases of excision would be more fairly classed with the cases treated by conservation in contradistinction to the cases treated by amputation. While this would somewhat change the relative percentages in the two groups of the upper and lower extremities, the conclusion arrived at above would remain the same, thus: Fractures of humerus, 8,245; treated by conservation or excision, 3,907, or 47.4 per cent.; fractures of bones of the forearm, 5,194; treated by conservation or excision, 3,956, or 76.8 per cent.; in the lower extremities, fractures of the femur, 6,738; treated by conservation or excision, 3,806, or 56.4 per cent.; and fractures of the tibia and fibula, 9,171; treated by conservation or excision, 4,326, or 49.1 per cent.

tation 25.8 per cent., showing that the fatality after excision exceeds that after amputation in the whole series of cases 1.7 per cent., although over three-fourths of the excisions were operations performed in the upper extremities, where the results of operative interference are less serious than in the lower extremities.

The greatest fatality after shot injuries of the extremities with lesion of bone was observed in shot injuries of the hip joint, where the fatality reached 84.7 per cent. Next came the injuries of the knee joint, with a mortality of 53.7 per cent.; then those of the thigh, of which 52.4 per cent. perished. Then come the injuries of the shoulder joint with 34.2 per cent. mortality, of the leg with 27.0, of the ankle joint with 26.9, of the arm with 20.7, elbow with 19.4, wrist 12.9, forearm 9.4, foot 8.3, and finally the shot injuries of the bony structure of the hand with 3.1 per cent. fatality.

A reference to TABLES CLXIII and CLXIV, *ante*, shows a percentage highly flattering to the efforts of conservation; but it must be borne in mind that the cases reported as treated conservatively were cases selected as specially adapted to this mode of treatment, and probably were the least serious. Moreover, there were many cases in which conservative treatment was abandoned and intermediary or secondary excisions and amputations were resorted to—cases which helped to increase the mortality rate of these operations, but which should properly be charged to the attempts at conservation. On the other hand, many operations were performed in the field, where the appliances and necessary rest of conservative surgery could not be had, and where frequent transportation for considerable distances was unavoidable, in which in general hospitals an attempt might have been made to save the limb.

The disposition towards conservation developed itself rapidly as medical officers became familiar with serious cases of shot injuries, and it is safe to say that in the later stages of the war many limbs were saved which at an earlier period would have been sacrificed. Especially was this the case in the upper extremities, where the preservation of the hand, or even of portions of the same, was considered most important for the well being of the individual. An examination of the many cases thus treated, as described in previous sections of the history, will show the formidable risks taken to attain this end.

There was a decided growth in the disposition to save in shot injuries of the lower extremities, especially in those of the femur, and the many favorable results leave beyond doubt the wisdom of the course. Still there was a wide difference of opinion on this point, particularly between field surgeons and those in charge of general hospitals at the rear—a difference that can only be reconciled by viewing the subject from the standpoint of each.

Probably the least satisfactory ultimate results of conservative treatment were those in the foot and ankle, which, while successful in saving life, render it doubtful, in the light of their ultimate condition, whether conservation was the wisest course.

EXCISIONS.—The consideration of this operation at this point is restricted to the excisions in the bones of the extremities; the three hundred and fifty cases of excisions in the bones of the head, face, and trunk, including two hundred and twenty instances of trephining, have been considered in the *First Surgical Volume*.

Of four thousand six hundred and fifty-six excisions, three thousand eight hundred and forty-one, or over four-fifths, were in the upper extremities, and eight hundred and fifteen in the lower extremities.

The excisions at the hip joint lead with the largest mortality, 90.9 per cent.; next come the excisions at the knee joint with 81.4 per cent.; the excisions in the shaft of the

femur have a fatality of 69.4 per cent.; the excisions at the shoulder of 36.6 per cent.; at the ankle joint of 29.0 per cent.; in the shaft of the humerus of 28.6 per cent.; in the tibia and fibula of 28.2 per cent.; in the bones of the foot of 19.3 per cent.; at the wrist joint of 13.8 per cent.; in the bones of the forearm of 11.3 per cent.; and in the bones of the hand of 9.6 per cent. With the exception of the elbow the excisions in the joints show

						2,800				982				392				482			

larger mortality rates than those in the osseous structures immediately above the joint; the fatality of the operations in the knee joint exceeds that in the shaft of the femur 12.0 per cent.; in the ankle joint the fatality is 0.8 per cent. greater than in the leg, and in the wrist joint 2.5 per cent. greater than in the bones of the forearm; the excisions at the elbow joint, on the contrary, show more favorable results than those in the arm, the death-rate being 5.6 per cent. less in the former than in the latter.

The percentage of fatality in the entire series of excisions in the extremities is disappointing, especially when it is considered that over four-fifths of the excisions were performed in the upper extremities, where the chances for success must be considered the brightest. It disproves the opinion held by the advocates of this operation that excision involves less loss of life than amputation. That it might be possible to obtain better results in well-appointed and less crowded hospitals is not denied; and the many excellent results obtained in civil practice should encourage the military surgeon to persevere in his efforts in this direction in suitable cases and under favorable circumstances. As to whether the effort made to secure a useful limb by excision compensates for the formidable risk which must be encountered in military practice, can be best determined by the reader by an examination of the analyses of the cases in the various sections of the extremities, as given previously under their appropriate headings. In brief, it may be stated that the results after excisions in the long bones and in the knee and ankle joints were little less than disastrous, and the ultimate conditions of many of these cases, although considered successful shortly after the operation, proved to be deplorable.

The results in excisions of the shoulder and elbow joints and, to some extent, in the wrist joint have been more encouraging, as useful limbs were preserved after many of these operations. In the excision at the wrist the patient generally recovered with anchylosis and extreme deformity of the hand and stiffness of the fingers; but such is the adaptability of the hand to all pursuits in life, that even with these disadvantages it remained a useful member to the patient.

In three hundred and five cases the excision was followed by amputation of the limb, in two hundred and twenty-six in the upper, in seventy-nine in the lower extremities.

The operations have been grouped into primary, intermediary, and secondary. The primary operations contain the excisions performed within the first three days; the intermediary those from the fourth to the thirtieth day, inclusive; and the secondary those performed more than thirty days after the date of injury. As indicated in TABLE CLXVI, the ratio of fatality after primary operations was 27.0 per cent., after intermediary 38.1, and after secondary 19.3 per cent. The results of the secondary operations were the most favorable; but it must always be remembered that this group embraces the cases only which had successfully resisted the attacks of the inflammatory period.

It will be noticed in the detailed histories of cases of excisions that the period of treatment extended over a long time, even months and years, and that these cases appeared to be particularly prone to consecutive hæmorrhage, gangrene, and pyæmia (see pages 808, 810, 825, and 857, *ante*).

Towards the latter part of the war the most thoughtful surgeons found it necessary to exercise a careful discrimination in the selection of cases for excision, and to refuse to operate in many instances in which, early in the contest, this operation would have been favored.

A table indicating the different months in which the operations were performed is here appended. The highest rate of mortality it will be noticed occurred in June, the lowest in November; but as regards the influence of season on the operations seemingly no points of value can be deduced from the tabular statement:

TABLE CLXVII.

Tabular Statement of Excisions, indicating the Months in which the Operations were performed.

AMPUTATIONS.—The total number of amputations reported on the records in this Office is twenty-nine thousand nine hundred and eighty (29,980); but the whole number of amputations performed for injuries received during the war would undoubtedly exceed that number. During the first eighteen months of the strife few or no reports were made of the wounded in the various engagements, and the hospital reports for this period were found to be very meagre. Furthermore, a number of amputations performed on officers treated in private quarters, and sometimes by their own family physicians, is unavoidably omitted in this summary, as no reports of these operations were ever sent to this Office. Another class of operations only partially included in this summary are late amputations, performed after the soldiers were discharged from service for wounds received during the war.

Of the twenty-nine thousand nine hundred and eighty (29,980) amputations the results were ascertained in all but one thousand seven hundred and nineteen (1,719), as shown in the following tabular statement:

TABLE CLXVIII.

Tabular Statement of Twenty-nine Thousand Nine Hundred and Eighty Amputations, indicating Seat of Operation and Results.

AMPUTATIONS.		CASES.				
		Totals.	Recoveries.	Deaths.	Results Unknown.	Percentage of Fatality.

	Amputations at the Shoulder Joint	866	596	245	25	29.1
Lower Extremities	Amputations of the Foot or Toes	1,519	1,317	81	121	5.7
	Amputations at the Ankle Joint	161	119	40	2	25.1
	Amputations in the Leg	5,523	3,595	1,790	138	33.2
	Amputations at the Knee Joint	195	82	111	2	57.5
	Amputations in the Thigh	6,369	2,878	3,411	80	54.2
	Amputations at the Hip Joint	66	11	55	....	83.3
Aggregates		29,980	20,802	7,459	1,719	26.3

Of the one thousand seven hundred and nineteen (1,719) undetermined cases, one thousand one hundred and fifty-three (1,153) were amputations of the hand or fingers, and but for the want of time and sufficient clerical assistance the results in nearly all these cases could have been ascertained. As it is, the number of cases in which the ultimate results are known is sufficiently large to determine the ratio of mortality attending the amputations in the various sections of the extremities. As in the excisions the operations at the hip gave the largest ratio of mortality, 83.3 per cent.; next come the amputations through the knee joint with 57.5 per cent., those of the thigh with 54.2 per cent., of the leg with 33.2 per cent., of the shoulder joint with 29.1 per cent., of the ankle joint with 25.1 per cent., of the arm with 23.8 per cent., of the forearm with 14.0 per cent., of the wrist with 10.4 per cent., of the elbow with 7.6 per cent., of the foot with 5.7 per cent., and of the hand with 2.9 per cent.

It will be noted that with the exception of the amputations at the elbow and those at the knee joint the ratio of mortality in the upper extremities as well as in the lower decreases with the increasing distance of the point of ablation from the trunk. No sufficient reason can be assigned for the exceptionally favorable results in amputations at the elbow; while the gravity of injuries as well as of operations in the knee has been repeatedly pointed out in this volume.

Comparing the mortality rate after amputations with that of excisions in the same portion of the extremities, we find the following results:

TABLE CLXIX.

Table indicating the Rate of Mortality after Amputations and Excisions in the Extremities.

UPPER EXTREMITIES—SEAT OF OPERATION.	RATIO OF MORT. AFTER—		LOWER EXTREMITIES—SEAT OF OPERATION.	RATIO OF MORT. AFTER—	
	Amputation.	Excision.		Amputation.	Excision.
Hand and Fingers	2.9	9.6	Foot and Toes	5.7	19.3
Wrist Joint	10.4	13.8	Ankle Joint	25.1	29.0
Forearm	14.0	11.3	Leg	33.2	28.2
Elbow	7.6	23.0	Knee Joint	57.5	81.4
Arm	23.8	28.6	Thigh	54.2	69.4
Shoulder	29.1	36.6	Hip Joint	83.3	90.9

With the exception of the operations in the bones of the forearm and those in the bones of the leg, the excisions are uniformly followed by larger percentages of fatality than the amputations, the excisions of the knee joint especially showing an exceedingly large excess in the mortality rate over the amputations at the knee. The favorable results after excisions in the bones of the forearm and leg are due to the fact that in many of these cases only portions of one or the other of the two bones comprising them were excised, thus lowering considerably the percentage of fatality of the operation. For instance, as shown on page 445, *ante*, the fatality after excisions in the fibula was 27.2, after those in the tibia 25.6, and after those in both bones was 61.1 per cent., while the average fatality of all the excisions in the bones of the leg is only 28.2 per cent. Similar results were obtained in the excisions of the bones of the forearm, the mortality after excisions of both radius and ulna exceeding those of the radius or ulna alone.

The necessity for a uniform system of classification of the amputations in order that the results of operations performed at different periods could be compared is self evident. All operations performed within forty-eight hours after the injury have here been grouped as primary, as the commencement of inflammatory symptoms rarely falls within this period. In the amputations at the hip joint alone the primary period has been restricted to twenty-four hours, as it is believed that in those cases the inflammatory period is hastened by the gravity of the injury. In the second or intermediary group have been placed the cases in which the operation was performed in the interval from the third to the thirtieth day (both inclusive) after the injury; this class consists mainly of the operations performed during the inflammatory stage. The third group comprises the operations performed after the thirtieth day from the date of the injury, or at a period when the inflammation had abated or entirely subsided.

Of the twenty-nine thousand nine hundred and eighty (29,980) amputations, the date after the injury on which the operations were performed was recorded in twenty-three thousand nine hundred and ninety-three (23,993) cases. Of these the results were not ascer-

tained in two hundred and thirty-one (231), leaving twenty-three thousand seven hundred and sixty-two (23,762) cases in which the results as well as the dates of operation and injury were recorded.

Sixteen thousand two hundred and thirty-eight (16,238) amputations belong in the group of primary operations performed within the first forty-eight hours; of these, three thousand nine hundred and ninety-two (3,992), or 23.9 per cent., terminated in death; five thousand five hundred and one (5,501) were intermediary operations; of these, one thousand nine hundred and eighteen (1,918), or 34.8 per cent., proved fatal; and two thousand and twenty-three (2,023) were secondary operations, performed after a lapse of thirty days from the date of injury, of which five hundred and eighty-four (584), or 28.8 per cent., had fatal terminations. The primary operations gave the best chance for life. The operations performed during the intermediary or inflammatory period were the most unfavorable in their results:

TABLE CLXX.

Summary of Twenty-three Thousand Seven Hundred and Sixty-two Amputations, indicating the period of the Operation.

	SEAT.	Cases.			Primary.			Intermediary.			Secondary.		
		Total.	Recoveries.	Fatal.	Recoveries.	Fatal.	Percentage of Fatality.	Recoveries.	Fatal.	Percentage of Fatality.	Recoveries.	Fatal.	Percentage of Fatality.

	Aggregates	.....	.....	.....	16,238			5,501			2,023		

Primary operations were the rule, over two-thirds of all the amputations belonging to this group. In the field, where few of the appliances of conservative surgery can be had, and where, moreover, the chances of properly applying them are uncertain, where, furthermore, transportation for considerable distances is unavoidable, frequently amputations are necessary where at least an attempt at conservation might be made in a general hospital. Nearly all the surgeons of the war agreed that the decision in regard to amputation should be made at the time of the injury and should be followed by immediate operation. In this connection Surgeon H. S. Hewit, U. S. V., observed that shock to the extent of forbidding surgical interference, even in cases of considerable gravity, is much less common than generally thought.

The experience with intermediary operations was so discouraging that when the time for primary operation had passed the operation, if possible, was deferred until the inflammation had subsided and the lesions had become local and analogous to chronic disease.

Of the different modes of operation each method had its advocates; but the flap operations were more frequently used, especially in amputations in and near the joints. Of eleven thousand and fifty-three (11,053) cases of major amputations in which the method is specified, six thousand two hundred and forty (6,240) were flaps, and four thousand eight hundred and thirteen (4,813) circular operations. A multitude of varieties of the flap operation were recorded; instances have been cited of the use of the anterior, posterior, antero-posterior, lateral, bilateral, external, internal, oval, circular, U-shaped, rectangular, and skin or muscular flap. In regard to the last two modifications it seems to have made little difference whether a thick covering of muscular tissue was used or a skin flap, for, as a rule, the stumps became conical sooner or later; short stumps sometimes remained well-rounded, long stumps rarely; but when they remained full it was often due to osteophytes, which in time became troublesome. The advocates of the circular operation claimed for this mode that it required little time and care in dressing, was easily handled, that it seldom sloughed, that its discharges were less, and that it was less frequently followed by hæmorrhage than the flap operation, while the latter mode would not stand transportation unless very carefully supported, and was considered, altogether, too nice an operation for the flurry of a battle-field. As far as the stumps are concerned, handsome rounded stumps were achieved by either method, as has been illustrated in PLATE LXXIII, opposite page 356, and conical stumps were noted after the circular as well as after the flap operation.

The side upon which the operation was performed was recorded in eighteen thousand seven hundred and eighteen (18,718) cases. The amputations on the left side exceeded those on the right by 3.4 per cent.—the operations on the left side being nine thousand six hundred and eighty-three (9,683), or 51.7 per cent., on the right nine thousand and thirty-five (9,035), or 48.3 per cent. of the cases in which this point was recorded. This is in accordance with the facts pointed out throughout the preceding volumes, that, with a few exceptions, the shot injuries of the left side were more numerous than those of the right.

TABLE CLXXI.

EXTREMITY.	Total Cases.	RIGHT SIDE.				LEFT SIDE.			
		Total.	Recoveries.	Fatal.	Percentage of Fatality.	Total.	Recoveries.	Fatal.	Percentage of Fatality.
Amputations in the Upper Extremities	7,628	3,655	2,845	810	22.1	3,973	3,127	846	21.2
Amputations in the Lower Extremities	11,090	5,380	3,138	2,242	41.6	5,710	3,326	2,384	41.7
Aggregates	18,718	9,035	5,983	3.052	33.7	9,683	6,453	3,230	33.3

Whether the seat of the injury was on the right or the left side seems to have had no influence on the ratio of mortality. In the upper extremities the fatality is slightly larger in the amputations on the left side; in the lower, in those of the right; but the difference in the rate of mortality of the two sides in the whole number is only 0.4 per cent.

The number of double amputations performed on account of shot injuries was one hundred and seventy-two; of these, both upper extremities were amputated in forty-seven, one upper and one lower in forty-three, and both lower in eighty-two, as follows:

TABLE CLXXII.

Numerical Statement of One Hundred and Seventy-two Cases of Double Amputations for Shot Injuries.

EXTREMITY.	TOTAL CASES.	RECOVERIES.	FATAL.	UNDETERMINED.	PERCENT. OF FATALITY.
Both Amputations in the Upper Extremities	47	31	16	.....	34.0
One Amputation in Upper, one in Lower Extremities	43	21	21	1	50.0
Both Amputations in the Lower Extremities	82	31	50	1	61.7
Aggregates	172	83	87	2	51.1

The mortality rate of the cases in which both the upper members were removed is 34.0 per cent., of those in which one of the upper and one of the lower extremities were amputated, 50.0 per cent., and of those in which the two operations were performed in the lower members, 61.7 per cent. Brief accounts of these cases will be found in the following table:

TABLE CLXXIII.

Condensed Summary of One Hundred and Seventy-two Double Amputations after Shot Injury.

No.	NAME, MILITARY DESCRIPTION, AND AGE.	DATE OF INJURY.	NATURE OF THE INJURY.	DATE OF OPERATION.	OPERATION AND OPERATOR.	RESULT AND REMARKS.
1	Warner, G. W., Pt., B, 20th Connecticut, age 32.	July 3, 1863.	Right arm severed from body 4 inches below shoulder, and left forearm fractured and lacerated by shell.	July 3, 1863.	Amputation of right arm at shoulder and left arm in lower third.	Discharged October 7, 1863.
2	Fuller, D., Pt., G, 53d Pennsylvania.	Sept. 17, 1862.	Shell wound, both arms	Sept. 17, Oct. 5, 1862.	Amputation at right shoulder joint and in upper third of left forearm.	Discharged Dec. 17, 1862; both stumps healthy and healed.
3	Mark, F., Pt., A, 2d Missouri Light Artillery, age 26.	May 26, 1861.	Both arms torn off by accidental discharge of a cannon.	May 26, 1861.	Amp. at left shoulder joint and in right forearm 3 ins. below elbow. Dr. Schmidt.	Discharged August 12, 1861; stumps in good condition.
4	Hodgdon, J. F., Pt., I, 1st Mass. Heavy Artillery.	June 14, 1863.	Both arms torn off to elbow and humeri fractured in several places from premature explosion of cannon; great laceration.	June 14, 1863.	Circular amputation of both arms in upper third. Surgeons M. F. Bowes, 12th Pennsylvania Cavalry, and T. C. Smith, 116th Ohio.	Discharged August 5, 1863.
5	Sergeant, W., Pt., E, 53d Pennsylvania, age 18.	June 1, 1862.	Shot fracture of both arms and wound of nose.	June 1, July —, 1862.	Circular amputation left arm in middle and right arm in upper thirds.	Disch'd November 19, 1864; sound stump.
6	Stratton, A., Pt., C, 147th New York, age 17.	June 18, 1864.	Solid-shot fractures of both elbow joints; laceration.	June 18, 1864.	Flap amputation both arms through middle. Surgeon A. S. Coe, 147th New York.	Discharged October 3, 1864; good stump. Died June 3, 1874; consumption.
7	Bacon, B. W., Capt., G, 74th Illinois, age 40.	June 27, 1864.	Shot fracture of right radius and ulna, and of left radius	July 14, 19, 1864.	Flap amp. middle third right arm. Surg. J. E. Herbst, U. S. V. In lower third l't arm. A. A. Surgeon J. H. Green.	Died July 21, 1864, of pyæmia.
8	Bawn, W., Pt., G, 16th Me., age 26.	Dec. 13, 1862.	Fracture of right arm by shell, and left arm by conoidal ball.	Dec. 14, 1862.	Amputation of both arms at junction of upper and middle thirds.	Died February 22, 1863.
9	Clarke, R., Pt., E, 13th Colored Troops, age 18.	Dec. 16, 1864.	Shot wounds of both arms, lower thirds; great destruction.	Dec. 16, 1864.	Right, upper third, flap; left, middle third, flap. A. A. Surgeon J. S. Giltner.	Died December 19, 1864.
10	Haltzee, F., Pt., F, 16th N. Y. H. A., age 21.	Sept. 1, 1864.	Both forearms carried away by a cannon ball.	Sept. 1, 1864.	Amputation in middle third of both arms. Surgeon M. S. Kittinger, 100th N. Y.	Died October 9, 1864; exhaustion.
11	Lacbine, L., Pt., D, 1st N. York Artillery.	June 18, 1864.	Hands blown off, eyes destroyed, humerus and forearm fractured; premature discharge of cannon.	June 18, 1864.	Amputation of both arms ...	Died June 20, 1864.
12	McHugh, O., Pt., D, 37th New York.	Dec. 13, 1862.	Shot fracture of both arms ..	Dec. 13, 1862.	Amputation of both arms ...	Died.
13	*Ruth, J.*, Pt., H, 6th Arkansas.	Nov. 30, 1864.	Shell fracture of both elbow joints.	Dec. 1, 1864, Jan. 2, 1865.	Right, ant. post. flap, lower third; left, antero-posterior flap, upper third. Surgeon Cooper, C. S. A.	Gangrene. Died March 26, 1865.
14	Savage, G., Pt., A, 2d Connecticut Artillery.	June 1, 1864.	Shot fracture of both arms by bullet.	On field.	Amputation of both arms ..	Died June 4, 1864
15	Tanner, T. B., Pt., B, 3d Rhode Island Artillery.	July 10, 1863.	Wound of both arms by premature explosion.	July 10, 1863.	Amputation of both arms ..	Aug. 5, hæmorrhage. Died August 9, 1863.
16	Vanatta, L., Pt., A, 23d Wisconsin.	Jan. 11, 1863.	Wound of both arms	Jan. 11, 1863.	Amp. of both arms. Surg. J. W. F. Gerrish, 67th Ind.	Died March 6, 1863.

No.	Name, Military Description, and Age.	Date of Injury.	Nature of the Injury.	Date of Operation.	Operation and Operator.	Result and Remarks.
17	Beatty, J. H., Pt., K, 5th Artillery.	July 3, 1863.	Right forearm and left arm at lower third carried away by premature discharge of cannon; fracture of jaw.	July 3, 1863.	Flap amputation of left arm at upper third and right forearm at middle third.	Discharged May 26, 1864; sound stumps.
18	Conner, J., Pt., F, 3d Delaware, age 15.	Feb. 2, 1863.	Compound fracture of right forearm, wound of left arm, and wounds of breast; accidental discharge of gun.	Feb. 2, May 26, 1863.	Amputation right forearm; dissecting aneurism of left brachial artery; amp. left arm, upper third. Surg. E. Wolfe and Asst. Surg. J. M. Houston, 3d Delaware.	Disch'd November 12, 1863; healthy stumps.
19	Duey, M., Pt., K, 97th Pennsylvania, age 21.	Jan. 15, 1865.	Shell fracture of right arm, middle third, and left forearm by conoidal ball.	Jan. 16, 1865.	Cir. amp. of right arm, upper third; left forearm at junct. upper and middle thirds.	Disch'd October 21, 1865; good stumps.
20	Hill, W., Sergt., A, 76th Colored Troops, age 29.	Apr. 4, 1865.	Fracture of right elbow and left forearm by a shell fragment.	Apr. 4, 1865.	Flap amputation right arm, lower third. Surgeon N. N. Horton, 47th C. T. Flap amputation left forearm, upper third. Asst. Surg. B. F. Lyford, 68th C. T.	Discharged July 22, 1865.
21	Maher, M., Corp'l, Detachment of Ordnance.	Sept 19, 1863.	Injured by explosion of a shell.	Sept. 19, 1863.	Amp. right arm, upper third; flap at middle third of left forearm. Surg. E. H. Abadie and Asst. Surg. H. L. Sheldon, U. S. A.	Discharged February 8, 1864; sound stumps.
22	Plunket, T., Serg't, E, 21st Massachusetts.	Dec. 13, 1862.	Shell wounds of both arms ..	Dec. 13, 1862.	Flap amputation right arm near shoulder, and left forearm in middle third.	Discharged, March 9, 1864.
23	Price, I., Corp'l, F, 15th West Virginia, age 34.	Oct. 13, 1864.	Shell fractures of both arms and flesh wound of thigh.	Oct. 14, 1864.	Amputation of right arm, lower third, and left forearm, upper third. Surg. W. S. Walsh, 15th W. Va.	Discharged June 9, 1865.
24	Shippen, S. C., Pt., D, 3d Rhode Island Heavy Artillery.	July 10, 1863.	Both arms mangled by premature discharge of gun; loss of right eye.	July 10, 1863.	Amputation right arm near shoulder, and left forearm near wrist. Asst. Surg. H. S. Lamson, 3d R. I. Art.	Discharged October 19, 1863.
25	Young, A. H., Pt., A, 6th Wisconsin.	Sept. 17, 1862.	Shot wounds of both arms .	Sept. 17, 1862.	Amp. in upper third of left arm, and flap amp. in upper third right forearm. Surg. J. McNulty, U. S. V.	Disch'd November 16, 1863.
26	Chatfield, J., Pt., E, 6th Ohio Cavalry, age 32.	June 21, 1863.	Shot compound fracture of left radius and right carpal and metacarpal bones	July 14, 1863.	Amputation at lower third of left arm and lower third of right forearm.	Died July 14, 1863.
27	Colwell, A. N., Pt., E, 1st Rhode Island Artillery.	Nov. 7, 1863.	Fracture of both forearms by premature discharge of cannon.	Nov. 7, 1863.	Amp. in lower third left arm and upper third right forearm. Asst. Surgeon H. G. Taylor, 8th N. Jersey.	Died November 7, 1863.
28	Ferris, G. W., Corp'l, A, 36th Wisconsin, age 34.	May 27, 1864.	Shell wounds of left arm, right hand, and left thigh.	May 27, June 12, 1864.	Circular amp. left arm, middle third; circ. amp. right forearm, upper third. A. A. Surg. W. B. Dick.	Died June 17, 1864, of pyæmia.
29	Walker, P., Pt., I, 104th New York, age 40.	June 18, 1864.	Shot fracture right humerus and left forearm by cannon ball.	June 18, 1864.	Musc. flap amp. at surg. neck right humerus, and circ. of left forearm in upper third.	Died July 9, 1864, of exhaustion.
30	McDonald, J., Pt., G, 85th Pennsylvania.	July 29, 1862.	Shell wounds of right arm and left hand.	July 29, 1862.	Amp. right arm near shoulder, and amp. at left wrist joint. Surg. S. A. Green, 34th Mass.	Discharged March 7, 1864; sound stumps.
31	Stanford, V. B., Pt., A, 1st Ohio L. A.	May 15, 1864.	Mutilation of hands by premature discharge of gun.	May 15, 1864.	Amp. at mid. third right arm and left wrist joint. Surg. E. B. Glick, 40th Indiana.	Died June 4, 1864.
32	Cassidy, J. E., Pt., K, 4th Artillery, age 33.	Mar. 31, 1865.	Left hand blown off and right wrist joint comm. by explosion of cannon; face and breast burned.	Mar. 31, 1865.	Oval flap amp. right forearm at mid. th'd and left forearm in upper third. Surg. W. S. Thompson, U. S. V.	Discharged July 21, 1865; both stumps perfectly healed.
33	Decker, S. H., Pt., I, 4th Artillery.	Oct. 8, 1862.	Wounds of both forearms by premature discharge of cannon.	Oct. 8, 1862.	Amputation both forearms six inches from elbow.	Discharged Nov. 3, 1862; good stumps.
34	Latham, E. P., Pt., 9th Battery Ohio Light Artillery.	June 19, 1862.	Both hands blown off by premature discharge of cannon.	June 19, 1862.	Amp. right and left forearms in upper third. Surgs. J. C. McPheeters, 33d Ind., and C. W. Millen, 2d Tenn.	Discharged Nov. 20, 1862; left stump sound, right withered.
35	Lewis, W. H., Pt., C, 5th Artillery, age 22.	June 7, 1864.	Compound fracture both forearms by explosion of a shell.	June 7, 1864.	Flap amp. upper third right forearm and lower third left forearm.	Discharged April 29, 1865; stumps healed.
36	Minor, E., Pt., F, Ind. Batt Minnesota Cavalry.	Sept. 28, 1864.	Injured by premature explosion of a cannon.	Sept. 28, 1864.	Ant. post. flap amp. low. th'd both forearms. Drs. Seward and Murphy.	Recovered. Stumps healed.
37	Shelby, T., Pt., E, 1st Ohio Heavy Artillery.	Apr. 10, 1865.	Comminution of both forearms, premature discharge of cannon.	Apr. 10, 1865.	Circ. amp. left, and flap amp. right forearm. A. A. Surgs. C. F. Thomas and W. Tibbetts.	Discharged June 22, 1865.
38	Tucker, J. B., Serg't, B, Green River Batt'n Kentucky State Militia.	July 4, 1865.	Severe injury both forearms and hands by ramrod from cannon.	July 4, 1865.	Circ. amp. right forearm near elbow and left near wrist. Asst. Surg. C. F. Ulrich, Kentucky State Militia	July 11, reamp. left forearm 4 inches below elbow. Discharged August 23, 1865; stumps healed.
39	Wallace, R., Pt., F, 33d Missouri.	May 18, 1864.	Shell wounds of both hands; great mutilation.	May 18, 1864.	Amp. right forearm in middle and left in lower third. Asst. Surg. C. H. Andrus, 128th New York.	Died on hospital steamer.
40	Magoonaugh, B., Pt., Ordnance Corps, age 23.	May 4, 1865.	Wounded while firing a salute.	May 4, 1865.	Circ. amp. mid. third right forearm, and flap amp. at left wrist. A. A. Surgs. E. S. Snow and D. O. Farrand.	Duty October 16, 1865.

114	Smith, H., Pt., I, 14th New Jersey, age 24.	June 7, 1864.	Shot wounds right thigh and left leg.	June 7, 1864.	Flap amputations at lower third right thigh and at left knee joint.	Died June 17, 1864.
115	Brown, H., Pt., K, 22d Colored Troops, age 19.	July 30, 1864.	Shell fracture both legs . ..	July 30, 1864, Mar. 19, 1865.	Amputation right leg in upper third; double flap amputation left thigh, lower th'd A. A. Surg. O. Shittler.	Discharged March 20, 1865. Died July 14, 1872.
116	Housley, H., Cook, F, 33d Wisconsin, age 20.	Apr. 2, 1865.	Shell fracture right knee joint and left leg, mid. th'd.	Apr. 11, 1865.	Amp. right thigh, lower th'd, and left leg in upper third; antero-post. skin flaps and circ. sect. muse. Surg. F. E. Piquette, 86th C. T.	Sent home July 23, 1865; not a pensioner.
117	Banks, S., Pt., C, 43d C. T.	July 30, 1864.	Conoidal ball fractured left leg and right thigh.	July 30, 1864.	Amp. mid. th'd r't thigh and of left leg, lower th'd. Surg. D. MacKay, 29th C. T.	Died July 31, 1864.
118	Bradley, P., Serg't, C, 16th Michigan.	Aug. 21, 1864.	Shell fracture left knee joint and right leg.	Aug. 21, 1864.	Amp. lower third left thigh and upper third right leg.	Died September 16, 1864.
119	Foss, J., Serg't, C, 59th N. York.	Sept. 17, 1862.	Shot wounds both legs and left arm.	Sept. 17, 1862.	Amputation of thigh and leg.	Died September 21, 1862.
120	*Hess, T. W.*, Pt., K, 8th North Carolina.	Sept. 30, 1864.	Shot fractures left leg and right thigh.	.....	Amputation of left leg and of right thigh.	Died October 7, 1864, of irritative fever.
121	Johnson, C. L., Pt., B, 1st Tennessee.	Aug. 6, 1864.	Compound shot fracture left leg, inv. knee joint, and right leg, lower third.	Aug. 6, 1864.	Amputation in low. third left thigh and upper third right leg.	Died August 21, 1864.
122	Lamphere, L. O., Pt., G, 21st Connecticut.	June 30, 1864.	Shell comminution lower end left femur and right foot and ankle.	June 30, 1864.	Amp. lower third left thigh and lower third right leg.	Died July 22, 1864, of tetanus.
123	*Lewis, J. R.*, Pt., H, 53d Georgia, age 32.	July —, 1863.	Shot wound left knee joint and fracture right leg.	July —, 1863.	Amp. left thigh, lower third; ri't leg at point of election. Surg. J. J. Knott, P. A. C. S.	Died July 10, 1863.
124	Birmingham, A., Lt., A, 69th New York.	Dec. 13, 1862.	Shot wounds right knee and left foot.	Dec. 13, 1862.	Amp. right thigh, and Pirogoff's amp. left ankle joint.	Died December 17, 1862.
125	*Alexander, J. W.*, Corp'l, K, 13th Mississippi.	Dec. 11, 1862.	Shot fracture both legs	Dec. 11, 1862.	Amputation of both legs. Surgeon Gilmore, C. S. A.	Recovered.
126	*Bartram, W. R.*, Pt., F, 1st North Carolina.	Sept. 17, 1862.	Shot fracture both legs	.... ..	Amputation of both legs ..	Furloughed Sept. 23, 1864.
127	Fisher, E. H., Lieut., A, 21st Indiana.	Oct. 20, 1862.	Wound of both legs by explosion of a shell	Oct. 20, 1862.	Amp. both legs. Surg. E. Read, 21st Indiana.	Discharged November 20, 1863.
128	Gordon, J., Teamster, Q. M. D., age 38.	Aug. 30, 1862.	Shell wounds both legs, low. third.	Sept. 1, 1862.	Amp. both legs, lower third. A. A. Surg. M. J. Davis.	Recovered.
129	*Higginbotham, E. B.*, Pt., F, 38th Georgia.	May 12, 1864.	Shot fracture of both legs...	May 13, 1864.	Amp. mid. third, both legs. Surgeon Arrington, C. S. A.	Recovered.
130	Kopp, E., Pt., K, 12th New Jersey, age 32.	Mar. 25, 1865.	Shot fracture of both tibiæ and left ankle joint.	Mar. 26, 27, 1865.	Flap amp. low. third right and mid. third left leg. Surgeons A. Satterthwaite, 12th N. J., and W. J. Burr.	April 16, protruding bones removed from stumps. Discharged Oct. 3, 1865.
131	[1] Lorence, J., Corp'l, K, 9th New Jersey, age 35.	Feb. 8, 1862.	Shot wounds of both legs by cannon ball.	Feb. 8, 1862.	Flap amputation both legs, up. third. Surgeons J. H. Thompson, U. S. V., and H. W. Rivers, 4th R. I.	Discharged September 30, 1862; 1875, knee joints without motion, stumps very tender.

CHAPTER XIII.

UNIVERSITY OF CALIFORNIA

ANÆSTHETICS.

It was impracticable to determine the total number of cases in which anæsthetics were employed during the war, but as near as can be ascertained they were used in no less than eighty thousand (80,000) instances. Time and clerical assistance did not allow of the examination of this enormous number of cases in detail, and in treating of this subject we must confine our remarks to the number of major operations in which the agents used were definitely ascertained. Of eight thousand nine hundred cases chloroform was used in six thousand seven hundred and eighty-four, or 76.2 per cent., ether in one thousand three hundred and five, or 14.7 per cent., a mixture of chloroform and ether in eight hundred and eleven, or 9.1 per cent. These percentages differ somewhat from the percentages given in the preliminary report,[1] where it was stated that chloroform was used in 60 per cent., ether in 30 per cent., and ether and chloroform in 10 per cent.; but at that time the percentage of the different agents had been principally derived from the reports of general hospitals, and in which ether was frequently used. When, afterwards, the operations performed in the field hospitals were examined, where chloroform was almost uniformly used, the percentage of the cases in which the latter agent was employed increased to 76.2 per cent., as above indicated, while the number of cases in which ether or the mixture of ether and chloroform was used was proportionally decreased.

The inestimable value of the use of anæsthetics in military surgery will hardly be denied at this date, although it has been claimed that the effect of anæsthetics in the treatment of shot injuries are deleterious, inasmuch as they add to the depression caused by the shock, and retard union by first intention, and predispose to hæmorrhages and pyæmia. It is possible that in two hundred and fifty-four cases in which it was asserted that no anæsthetic was given the surgeons were actuated by such objections, as no reasons have been assigned why anæsthetics were not administered. How far the use of anæsthetics has contributed to the saving of life during the late war it is impossible to say, as we have no statistics to make this comparison. It may be stated, however, that their use has undoubtedly influenced the favorable percentages of mortality after major operations pointed out in different sections of this and the preceding volumes.

From the rapidity of its effects, and from the small quantity required—qualities which can only be appreciated at their proper values by the field surgeon when surrounded by hundreds of wounded anxiously awaiting speedy relief—chloroform was preferred by nearly

[1] *Circular* No. 6, War Department, Surgeon General's Office, Washington, November 1, 1865.

all the field surgeons, and their testimony as to its value and efficacy is almost unanimous, although all recommend the greatest care in its administration. It is, perhaps, best to allow the different medical officers to speak for themselves on this subject: Surgeon C. J. Walton, 21st Kentucky, administered "chloroform in every painful operation, but did not keep the patients under its influence longer than was absolutely necessary, withdrawing it as soon as the cutting was completed. * * * While I could not dispense with chloroform, I must protest against the extravagant and indiscreet use of it. It is a most potent agent, and should be used with the utmost caution. *In no case were we displeased with its effect.*" Surgeon B. B. Breed, U. S. V.: "Chloroform was almost universally employed as an anæsthetic, and without bad effect in any case. Whenever practicable, I employed ether in preference to chloroform, preferring, both from personal experience and observation, the delay and discomfort in its administration to the possible danger from the use of the latter. On the field of battle, however, chloroform is the safe and preferable agent." Assistant Surgeon C. Bacon, jr.: "The anæsthetic I have seen used has invariably been chloroform. Among the great number of cases in which I have witnessed its administration I have seen but one death resulting from its use. I have, however, frequently seen cases in which its use required extreme care, and, at times, have been obliged to desist in its administration in cases of great exhaustion consequent upon long-established injuries. I have frequently seen the use of chloroform attended with bad results when improperly administered. As an anæsthetic I think chloroform should be given in prompt and efficient dose. The desired effect being attained, its administration should be discontinued; in this manner less chloroform is required, thereby avoiding to a great extent its toxical effect." Surgeon D. P. Smith, U. S. V.: "I have in every instance but one, in the army, employed chloroform, and in but one case have I had reason to believe its use disastrous. In this instance it was given too profusely by an entirely incompetent person (since then dismissed from the medical corps) while I was amputating at the knee joint. The patient never reacted from the shock, but died about twelve hours subsequently." Assistant Surgeon J. T. Calhoun, U. S. A.: "I have always used chloroform as an anæsthetic, have given it, and have seen it given under my direction, and in the practice of other surgeons in an immense number of cases, and never saw a death from it, or, in army practice, even an alarming symptom. I am inclined to believe that in general practice the chief danger of choloform is that in its administration care is not taken to let the patient inhale sufficient air with it (a fact often due to the desire to be economical in its use), and the patients die, not from the chloroform, but from the want of oxygen." Surgeon H. S. Hewit, U. S. V.: "Chloroform was used freely without any fatal accident. But I conceived that those cases did not finally do so well who were kept under its influence for a length of time; and I am of the opinion that when used the patient should be kept under its influence merely long enough to last through the severest part of the operation. I believe that when a patient is kept under its influence for a long time his chances of recovery are thereby lessened." The serious results following the use of chloroform, when "improperly" or "too long" administered, or when administered by "incompetent persons," referred to by several of the operators, will hardly be charged to the agent itself. In the reports of the surgeons in charge of base hospitals, sometimes the use of ether, sometimes of chloroform alone, or a mixture of both, is advocated.

The most convenient and common form of administering anæsthetics was a cloth or paper folded in the shape of a cone, with a sponge in the apex. It was placed at some distance

over the nose and mouth of the patient to allow the first inhalations to become diluted with air, and then gradually advanced to the nose until anæsthesia was produced, when the inhalation was suspended. The method of Marshall Hall, by placing a double fold of muslin over the mouth and nose of the patient and simply dropping the chloroform on it drop by drop, was found to be tedious, and inoperative in the open air, where many of the operations were performed, owing to rapid evaporation. In the southern armies, where chloroform was scarce, Surgeon J. J. Chisolm, finding that much chloroform was wasted by these methods, employed a flattened cylinder two and a half inches long and one inch wide in its broadest diameter, having in one of its broadest surfaces a perforated plate. Attached to the cover are two nose pieces. When the instrument is not in use these projections can be pressed into the cylinder, thus diminishing the size of the instrument. In the interior of the cylinder is found a piece of sponge, or what is much better, a bent wire, over which is folded a piece of cotton cloth. The chloroform when dropped through the perforated plate is received upon the sponge or folded cloth, which offers an extended surface for evaporation.

FIG. 424.—CHISOLM'S Inhaler. *Spec.* 4910.

In reference to the propriety of giving alcoholic stimulants prior to the administration of ether and chloroform, the records of the war supply little definite information. They give simply the number of cases in which anæsthesia was induced, and frequently not even the name of the anæsthetic employed. In cases in which the effect of the anæsthetic was believed to have led to a fatal result special reports were made. These special reports throw little light on the question, since they include, in almost equal proportion, cases in which stimulants had, or had not, been administered prior to the inhalation of the anæsthetic. Some surgeons advise the use of stimulants prior to anæsthesia uniformly; others deprecate the practice except in rare cases, and others again discard it altogether. When there is extreme depression, alcoholic stimuli will of course be employed, in conjunction with other restoratives, to bring about reaction. But when the patient is in a fit state to undergo a major operation, a stimulant should not be given with especial reference to the anæsthesia about to be induced, as it would seem that in the practice of surgeons who habitually employed the stimulants the patients were less readily anæsthetized. It would be better to reserve the stimulant as a restorative in the course or on the completion of the operation, that it may aid in reducing reaction instead of retarding the induction of anæsthesia.

It has been stated that the nature of the anæsthetic employed was indicated in eight thousand nine hundred cases, viz: chloroform in six thousand seven hundred and eighty-four, ether in one thousand three hundred and five, and chloroform and ether in eight hundred and eleven cases. Of the six thousand seven hundred and eighty-four cases in which chloroform was used, death was ascribed to this agent in thirty-seven, or 5.4 per thousand;[1] of the one thousand three hundred and five cases in which the anæsthesia was induced by ether, four deaths, or 3.0 per thousand; and of the eight hundred and eleven cases in

[1] CHISOLM (J. J.), (*A Manual of Military Surgery for the use of Surgeons in the Confederate States Army*, Columbia, 1864, pp. 429–30): "Of the many thousand instances of its administration since the war between the Confederate States and United States began, but two fatal cases from chloroform inhalation have been reported. In one, the patient died in a few minutes after inhalation was commenced. In the other, the patient did not die for several hours. The case was that of a healthy young soldier who had a minié ball embedded under the scapula, and who, while *en route* to rejoin his command, stopped at a hospital and desired its removal. The operation was very tedious, and he was kept under the influence of chloroform for one and a half hours. Although he regained his consciousness when the administration was stopped, his pulse never reacted, notwithstanding the liberal use of brandy. A few hours after the operation was completed there appeared an increasing disposition to sleep, which gradually ended in coma, the pulse becoming more and more feeble. He died thirty-two hours after the inhalation. As the operation affected no vital part, and as the health of the patient was good, his death could be attributed to no other cause than the inhalation of the chloroform."

which a mixture of chloroform and ether had been employed, two deaths, or 2.4 per thousand, were charged to the anæsthetic. Brief abstracts of the fatal cases are given.

Deaths from Chloroform.—Thirty-seven cases were reported:

CASE 1233.—Surgeon M. K. Hogan, U. S. V., reports that Private Sylvester Anninger, Co. F, 147th New York, aged 27 years, received a shot fracture of the left leg, at Spottsylvania, May 12, 1864. He was at once carried to the field hospital of the 3d division, Ninth Corps. He died May —, 1864, "under chloroform."

CASE 1234.—Corporal ——— Ballou, Co. E, 14th Pennsylvania Cavalry, fracture of bones of right hand, April, 1863. Operation for removal of fingers October 12, 1863. Chloroform inhaled without unpleasant symptoms; upon removing index finger pain was evinced; small additional portion given and operation recommenced, when patient struggled violently; arterial hæmorrhage ceased to flow; tongue found to not have fallen back upon rima glottidis; usual means of exciting respiration applied; good current of fresh air; patient rolled from side to side; artificial respiration resorted to; spirit of ammonia applied to nostrils and cold water dashed on chest and face, without effect. In the opinion of Surgeon W. B. Wynne, 14th Pennsylvania Cavalry, the operator, the patient was not under the effects of the anæsthetic five minutes before life was extinct. At the autopsy the lungs were found to be perfectly healthy; the heart presented some appearance of slight ossification.

CASE 1235.—Private *J. Bradley*, Co. D, 25th North Carolina; slight wound of patella; admitted into Chimborazo Hospital, Richmond, June 25th; necrosis and gangrene. July 18th, amputation at junction of upper and middle thirds of thigh. There was but little blood lost, but the patient sank under the operation and expired a few minutes after its completion. It is remarked, upon an unsigned case-book, that "the chloroform may have, by its depressing effect, contributed to this unfavorable result, for it caused him to vomit freely, and he was unable to retain any stimulants in the stomach."

CASE 1236.—Private G. Budlinger, 76th Ohio, aged 30 years, admitted into hospital of 1st division, Fifteenth Corps, with a shot wound of hand; placed upon operation table and about a drachm of chloroform sprinkled upon four folds of patent lint applied to face, space being given for the free admission of air. After breathing it for a few moments quietly without any apparent effect, more chloroform was added and reapplied by a nurse in attendance (the surgeon having stepped aside for a moment), when, after six or seven respirations, the patient drew up his legs and arms convulsively, and heavy stertorous breathing came on. Chloroform removed immediately, and a few moments given him to resume his regular breathing, but the difficulty increased; frothy exudation from mouth not caused by excess of saliva; respiration became more and more incomplete, pulse small and imperceptible, veins of neck and face prominently distended; heart action ceased before respiration had entirely stopped. Friction to extremities, cold water dashed in face, jugular vein opened, artificial respiration, without relief. The surgeons of the hospital reported, as the result of an autopsy, that "being unable to discover any other abnormal condition, and in the absence of further evidence, it may be proper to conclude that this is a case of apoplexy induced by chloroform."

CASE 1237.—Private J. G. Clarkson, Co. A, 35th Massachusetts, age 40 years, is reported by Surgeon F. M. Lincoln, 35th Massachusetts, to have died in hospital at Falmouth, Virginia, "from the inhalation of chloroform administered for the performance of an amputation," January 20, 1863.

CASE 1238.—Private J. Conley, Co. A, 90th Illinois, aged 18 years; shot fracture left ankle joint, Mission Ridge, November 25, 1863; ball lodged; admitted into hospital No. 1, Nashville, February 4, 1863. Surgeon R. L. Stanford, U. S. V., reports that the patient "died from the effects of the chloroform at the time of the operation of extraction of the ball," and forwarded the specimen of the lower portions of the left leg, the astralagus, and calcaneum; they constitute *Spec.* 3360 of the *Surgical Section.*

CASE 1239.—Private P. Conlin, Co. G, 11th New Jersey; shot perforation knee joint, popliteal artery cut; Ream's Station, September 17, 1864; considerable hæmorrhage; patient in a very nervous state and having great fears of the result. Stimulants were given, and after he had rallied a little he was placed upon the table and chloroform administered. Plenty of fresh air was allowed during the administration and he passed through the usual stages necessary to insensibility, but died before the contemplated operation was commenced, having just reached the point of insensibility. The only observable symptoms which were unusual were the high state of nervous excitement while the chloroform was being administered and the very small quantity required to render him insensible. Methods for resuscitation freely used for half an hour without effect. A *post-mortem* examination revealed nothing abnormal in the size or appearance of the organs.

CASE 1240.—Sergeant *S. Crumbaker*, Co. A, 35th Virginia Cavalry, aged 44 years, was admitted into the Confederate hospital at Charlottesville in May, 1864, with a pistol ball perforation of the head of the humerus, received at the Wilderness, May 6th. On May 11th chloroform was administered and the head of the humerus was excised. He is reported to have died May 16, 1864, "from the effects of the chloroform."

CASE 1241.—Private T. Donaldson, Co. E, 13th Ohio Cavalry, aged 19 years; shot injury left humerus, Poplar Springs, Virginia, October 8, 1864; admitted into hospital at Beverly, New Jersey. Necrosis of humerus. October 29, 1864, amputation of left arm at shoulder by antero-posterior flaps by Acting Assistant Surgeon J. C. Morton; chloroform used. Patient "died from the effects of the chloroform and nervous shock to the general system." The upper part of the humerus was forwarded to the Museum by Assistant Surgeon C. Wagner, U. S. A., and is numbered *Specimen* 3706 of the *Surgical Section.*

CASE 1242.—Private D. Flynn, Co. A, 18th Infantry, admitted into hospital No. 19, Nashville, January 5, 1863, with a compound fracture of fingers of right hand, received December 31, 1862. January 8th, chloroform administered with a due proportion of atmospheric air; patient was rather troublesome, struggled, etc. A relaxation of the muscles testifying to anæsthesia, the chloroform was suspended and the operation commenced; just after the formation of the anterior flap the patient commenced to breathe stertorously, and at that instant the brachial pulse suddenly ceased; there was an up and down movement of the thyroid cartilage, a swelling out almost to bursting of the external jugular veins, blue lips, a pupil insensible to light, and an ashy paleness. Cold water dashed in face, aqua ammonia to nostrils and upon thorax, tongue drawn forward with tenaculum.

artificial respiration kept up, and the principles of Marshall Hall's method of respiration put into requisition, but without effect; patient expired after one or two long-drawn sighs. Amount of chloroform expended was about two drachms. No autopsy possible.

CASE 1243.—Private R. Gormley, Co. I, 7th New York Artillery, admitted into McClellan Hospital, Philadelphia, June 13, 1864, with a shot wound of the lower third of the right leg; ball lodged. On November 29th chloroform was administered with a view of removing the ball. The anæsthetic was given with great caution, and inhaled with perfect facility until the operation was nearly completed. Acting Assistant Surgeon W. E. Ely stated that "the patient's pulse continued good, and nothing of unusual interest presented itself until the incision had been made, when I was suddenly deterred from proceeding in search of the ball by a spasmodic rigidity of the muscles, such as generally occurs immediately before the point of complete anæsthesia is attained. The patient, who had up to this time appeared perfectly sensible of external objects, suddenly threw his head back and almost immediately expired. Cold water was dashed into his face, ammonia was applied to his nostrils, his mouth was kept open, and his tongue drawn forward, while Hall's ready method of artificial respiration was kept up for nearly an hour, but only with the effect of producing three or four long inspiratory efforts, when life became entirely extinct." Dr. Ely was assisted by Acting Assistant Surgeon A. S. Uhler.

CASE 1244.—Private Thomas Hamilton, Co. A, 1st Maryland Infantry, aged 31 years, admitted into Patterson Park Hospital, Baltimore, June 25, 1864, with a gunshot wound of the hand. September 3, 1864, patient placed on table to undergo an operation for necrosis of the carpal bones. A sponge wet with chloroform was carefully held at first some three or four inches from the face, and at no time less than two or three inches. The patient inhaled for about five minutes and still remained conscious, frequently making some remark. He soon, however, commenced muscular efforts, such as are quite common with patients inhaling chloroform, except that the muscular contractions were more violent than usual. Before the contractions ceased the pulse grew feeble and the chloroform was withdrawn for two or three minutes; the breathing continued regular, only that the patient occasionally took a deep inspiration and expired forcibly, then the muscles became relaxed; the operation was commenced; but the respiration soon commenced to fail and the pulse became imperceptible; the operation was stopped. All known means for resuscitation were resorted to, but life had fled. The friends of the deceased could only be persuaded to allow an examination of the heart. The organ was found of normal size and appearance; both auricles were distended with venous blood, but the ventricles were empty. A clot of white fibrin, streaked in some places with coagula of blood, was found in each auricle.

CASE 1245.—Private Robert Harris, Co. G, 132d New York, was admitted into Ward Hospital, Newark, New Jersey, May 4, 1864. Surgeon George Taylor, U. S. A., reported that the patient died on May 20, 1864, while under the influence of chloroform administered for the purpose of amputating the leg.

CASE 1246.—Private John Johnson, Co. B, 2d Pennsylvania Heavy Artillery, a patient in Mower General Hospital, near Philadelphia, expired suddenly on May 13, 1865, while inhaling chloroform preparatory to undergoing a surgical operation. The case is reported by Surgeon J. Hopkinson, U. S. V.

CASE 1247.—Private John Kroft, Co. D, 7th New York, shot fracture leg, Petersburg, September 16, 1864. Admitted into hospital at Beverly, New Jersey, September 28th. Amputation of leg October 8th. On November 16th a second amputation was found necessary; at the previous operation sufficient chloroform was administered to produce complete anæsthesia without unpleasant effect. On the latter date chloroform was administered on a sponge, from one drachm to a drachm and a half—in all not over an ounce was given. He had been upon the table about fifteen minutes when fatal symptoms were manifested, and he died in from five to six minutes. An autopsy revealed no pathological lesions sufficient to account for death. Assistant Surgeon C. Wagner, U. S. A., reported the case.

CASE 1248.—*William Laws*, Co. E, 23d North Carolina, aged 24 years, shot wound of groin, fracturing tuber ischii; admitted into hospital No. 1, Frederick. October 28th, chloroform was administered to remove the fragments of the ischium. The chloroform was administered on a pocket handkerchief which was pressed firmly against the mouth of the bottle which was then inverted. Plenty of air was given, and the handkerchief was wet with chloroform but once. About a minute after the administration was begun almost complete relaxation was produced, and two stertorous respirations were observed, when the handkerchief was immediately removed. The pulse up to this time was undisturbed; the patient then took some ten or twelve deep and rather rapid inspirations, with quickened pulse, when respiration suddenly ceased; the pulse continued for six or eight beats, which were slower and feeble, and then suddenly ceased. Artificial respiration was immediately resorted to by Marshall Hall's ready method, which produced distinct respiration, but no pulsation. Having kept it up for about twenty minutes without result, the case was given up as hopeless. An account of the *post-mortem* appearances, together with other details of the case, will be found in CASE 703, page 242, *Second Surgical Volume*.

CASE 1249.—Colonel McGilvray, Chief of Artillery of the Tenth Corps, was slightly wounded in the forefinger of the left hand, at Flussus Mills, August 17, 1864. Excision of the joint was advised, and, on September 4th, chloroform was administered; about a drachm of the anæsthetic was poured on a sponge enclosed in a towel folded funnel-shaped. The patient came very kindly under its influence, about two drachms of chloroform in all being used. The period of excitement did not last over a minute and a half. The operation was commenced; the pulse was then beating steady and firm at about 65, respiration slow and regular; at the time the inhalation of the chloroform had been discontinued for at least two minutes; at the moment of the first incision the pulse and respiration at the same moment ceased without the slightest warning. The face flushed for a moment, and then became pallid; the eyes were fixed and not suffused. About half a minute after the cessation of respiration the patient made one or two spasmodic attempts at respiration and then was still. Artificial respiration was commenced and kept up for an hour, but in vain. The heart and lungs were examined on the next day, but did not indicate the cause of death. The particulars of the case were communicated by Surgeon A. M. Clark, U. S. V.

CASE 1250.—Sergeant George S. Moss, Co. C, 125th New York, received a shell wound of the penis, scrotum, and thigh, at Gettysburg, July 3, 1863; the missile lodged among the muscles of the back of the thigh. The patient desired to have the

missile removed, but positively refused to be touched without the administration of chloroform. On August 8th a stimulant was given and the anæsthetic was administered; in one minute the patient came under its influence, the shell fragment was removed in less than half a minute, and additional stimulant administered; pulse became suddenly weak, and the patient died almost instantly. It was the opinion of surgeons present that the patient died from valvular affection of the heart.

CASE 1251.—Private Patrick Murphy, Co. B, 111th Pennsylvania, aged 22 years, admitted into hospital at Murfreesboro', Tennessee, October 28, 1863, with shot wounds of right knee joint and in centre of forehead, received at Brown's Ferry, Tennessee, on the same day. On admission patient was wild, delirious, and unruly, but a few hours afterwards seemed partially to recover his senses. On October 30th amputation of the thigh was performed. On loosening the tourniquet no blood escaped from the vessels, and the patient was observed to be in a state of collapse. Stimulants were freely given, but without avail. He died on the table soon after the operation, probably from the effects of chloroform. A section of the anterior portion of the cranium, showing a partial fracture and depression of the centre of the frontal bone, was forwarded to the Museum by Assistant Surgeon John C. Norton, U. S. V., and is numbered 2139 of the *Surgical Section*.

CASE 1252.—Private C. M. Odell, Co. I, 36th Wisconsin, received a shot fracture of the head and shaft of the humerus, at Cold Harbor, June 3, 1864. Amputation was deemed necessary; his pulse was good, and he walked to the operating table unassisted. Chloroform was given until complete relaxation of the voluntary muscles was produced; the amputation was performed, the arteries ligated, and the flaps were about to be closed, when respiration suddenly and quietly ceased. Artificial respiration was set up, but without success. The autopsy showed the heart much enlarged, without thinning of the walls, and distended on both sides with a grumous fluid and tough grayish clot, which extended into the great vessels.

CASE 1253.—Surgeon J. F. Patterson, 131st New York, states that "on June 11, 1863, the 114th New York was ordered to take a position in front of our line, and while advancing to execute the order one of the privates shot himself in the foot and was carried to the field hospital for treatment. An amputation being deemed necessary, chloroform was administered by the assistant surgeon of the 1st Louisiana in such a manner that death almost immediately ensued. The surgeon of the 114th, whose name I believe was Wagoner, opened the chest of the cadaver about fifteen minutes after death, and finding the lungs lying on the back of the chest announced that death was occasioned by collapse of the lungs." The case of William Rathbone, Co. K, 114th New York, who received a gunshot wound of toe of left foot at Port Hudson, Louisiana, and who died, is reported by Surgeon L. P. Wagner, 114th New York, but no details of the case are furnished.

CASE 1254.—Surgeon S. A. Richardson, 13th New Hampshire, in a special report of the surgical operations performed at Flying Hospital, Twenty-fourth Corps, March 30th to April 9, 1865, remarks: "Manuel Silver, Private, Co. F, 10th Connecticut, gunshot comminuted fracture of the left humerus by conoidal ball. Flap amputation left arm in middle third by Surgeon H. C. Levensaler, 8th Maine, April 2, 1865 (primary operation). Died during the operation, from effects of chloroform given by Surgeon De Landre, 158th New York. Was brought under the influence of chloroform with difficulty."

CASE 1255.—Sergeant Major Adolphus Spaeth, 9th Ohio, was admitted into Cumberland Hospital, Nashville, September 24, 1863, with a shot fracture of the right wrist. The ball passed upward on the palmar aspect of the forearm nearly to the bend of the elbow, but so deeply embedded as not to be found. He had violent erysipelas of arm and great constitutional disturbance. Three or four days afterwards the ball was removed from the deep layer of muscles opposite the upper third of the radius, palmar aspect. His general condition continued bad. On October 17th he was placed upon the table for amputation at the middle third of humerus. During the administration of chloroform death took place with scarcely a premonitory symptom. The *post-mortem* exhibited venous congestion of both lungs, evidently produced by the chloroform, the lungs being otherwise perfectly healthy. The quantity of chloroform inhaled did not exceed two drachms.

CASE 1256.—Private George E. Stannard, Co. G, 14th Connecticut, admitted into Finley Hospital, Washington, with a shot fracture of left ulna, received at Fredericksburg December 31, 1862. Patient was a perfectly healthy, robust man, of lively temperament, rather pale in color. On January 28, 1863, chloroform was administered for the purpose of removing the loose pieces of bone. About two drachms of the anæsthetic were sprinkled on a towel and placed to the nose; in about five or six minutes he came under its influence; the usual struggle came on just preceding complete anæsthesia, when he suddenly ceased to breathe and his pulse failed. Every effort to resuscitate him failed. The history of the case, together with the specimen of the lower extremity of the left ulna, was contributed by Surgeon I. Moses, U. S. V.; the *Specimen* is numbered 859 of the *Surgical Section* of the Museum.

CASE 1257.—Corporal C. F. Tarbell, Co. D, 21st Maine, aged 19 years, shot wound of left thigh, at Port Hudson, May 27, 1863. He was removed to the regimental hospital, where it was found necessary to amputate the thigh in the middle third. Surgeon G. E. Brickett, 21st Maine, reports that the patient died May 27, 1863, from the effects of the chloroform.

CASE 1258.—Private G. N. Titus, Co. G, 8th Vermont, was admitted into regimental hospital at Algiers, Louisiana, August 21, 1862, with a wound of one of his toes. Chloroform was administered by Surgeon H. H. Gillett and Assistant Surgeon S. H. Currier, 8th Vermont, for the purpose of amputating the injured toe. The patient expired suddenly, before the operation was commenced. Assistant Surgeon L. C. Herrick, 4th U. S. Colored Cavalry, reports the case.

CASE 1259.—Surgeon Edwin Bentley, U. S. V., reports that a Confederate soldier, a large, robust, muscular North Carolinian, after the battle of Hanover Court House, May 29, 1862, underwent amputation of the thigh. The operation was performed in the open air and very little blood was lost. A large amount of chloroform had been administered without the patient becoming at all unconscious, when the surgeon forced him to large and free inspirations and he became immediately under its influence. Just after the completion of the operation the pulse sank rapidly, and he appeared to cease to breathe simultaneously with the effects of the anæsthetic.

CASE 1260.—Surgeon John A. Lidell, U. S. V., in his report of the operations of the medical staff of General Sedgwick's division of the Second Corps, at Fair Oaks, states: "A soldier of General Richardson's division was placed on the table and

chloroform administered for the purpose of amputation of the thigh for gunshot comminuted fracture of the femur in the neighborhood of the knee joint. While inhaling the chloroform he suddenly became pale, pulseless, and ceased to breathe, dying on the operating table while the amputation was going on."

CASE 1261.—Private J. W. Whitlock, Co. K, 111th Illinois, gunshot wound of left elbow joint, Dallas, Ga., May 31, 1864. Admitted into hospital of 2d division, Fifteenth Corps, same day; chloroform administered for the purpose of operating, but he died from its effects. An autopsy revealed extensive adhesions of the pericardium and hepatization of the right lung. The case is reported by Surgeon J. B. Potter, 30th Ohio.

CASE 1262.—Unknown soldier, with a shot injury necessitating amputation at the knee joint; chloroform was administered, and the patient died while the operation was being performed. Surgeon D. P. Smith, U. S. V., the operating surgeon, states that the anæsthetic was administered too profusely by an entirely incompetent person, who was subsequently dismissed from the service.

CASE 1263.—Corporal A. Wilde, Co. H, 61st New York, wounded at Deep Bottom, August 19, 1864; distal phalanx of thumb shattered; admitted into hospital of 1st division, Second Corps. Assistant Surgeon C. Smart, U. S. A., reports that chloroform was given, and after about three drachms had been taken the patient became much excited and passed into a violent convulsion, in the midst of which he died. At the autopsy the heart was found small and firmly contracted, its walls being in contact and the cavities obliterated.

CASE 1264.—Private Lewis Winters, Co. I, 11th Michigan, aged 40 years, Atlanta, August 7, 1864; conoidal ball in upper third right thigh. Admitted into hospital No. 8, Nashville, August 20th; gangrene. October 27th, preparatory to cleaning and burning the wound Acting Assistant Surgeon R. W. Forrest commenced to administer chloroform from a sponge surrounded with a napkin, plenty of atmospheric air being admitted. Not more than half an ounce of chloroform was poured upon the sponge. His pulse was good, and he was judged to be a healthy man. After inhaling the chloroform for about three minutes a very severe spasm came on; his head was thrown violently back, his body arched, resting on top of head and feet, the arms were drawn up, and the hands violently clenched. The chloroform was withdrawn; the spasm relaxed in a few seconds; his head and face became very much congested. Cold water was instantly dashed over his face and chest and ammonia applied to the nostrils, and every means that could be devised to resuscitate kept up for more than an hour without effect. Autopsy: Five points of cicatrization from scarification for cupping; considerable serous effusion under arachnoid and filling sulci; vessels on surface of brain much congested; pleuritic adhesions very firm on both sides; left lung deeply engorged with dark blood, frothy serum exuding from cut surface, and numerous small chalk-like deposits found near the surface; heart normal in size and appearance.

CASE 1265.—*D. Zebriske*, Co. I, 12th Alabama, admitted into hospital No. 5, Frederick, October 18, 1862, with a shot flesh wound left hip, traversing deep portion of gluteal muscles; Antietam, September 17, 1862; ball lodged. October 19th, chloroform administered with a view of removing missile. No unusual symptom was observed; but while the operation was in progress and the patient not in the act of inhaling the vapor, it was discovered that he had ceased to breathe. The autopsy threw no light on the cause of death. The subject was anæmic, and exhausted by hardship and depleted by suppuration. The report of the case was made by Surgeon H. S. Hewit, U. S. V.

CASE 1266.—Private G. G. Allison, Co. A, 6th New York Artillery, aged 43 years, admitted into hospital at Beverly, New Jersey, July 7, 1864. On February 7, 1865, he was placed upon the table to be operated on for fistula in ano. Chloroform was administered in the ordinary manner; room was well ventilated and the vapor of the chloroform freely diluted with atmospheric air; full anæsthesia was produced, when the pulse rapidly failed, and in a very brief period death took place. The quantity of chloroform inhaled did not exceed two drachms. Every effort was made to restore life by artificial respiration, ammonia, stimulants, etc. An autopsy was made twelve hours after death; the brain, thoracic and abdominal viscera were very carefully examined, but nothing detected sufficient to account for death; the brain was very slightly congested. Assistant Surgeon C. Wagner, U. S. A., reported the case.

CASE 1267.—Private Francis Heward, Co. F, 1st New Jersey, was admitted into Fairfax Seminary Hospital, April 5, 1862, with a dislocation of left humerus forward and inward of a few hours' standing. Surgeon Henry A. Armstrong, 2d New York Artillery, reduced the bone without assistance. On May 6th Acting Assistant Surgeon H. W. Ducachet discovered that the bone was again out of place in the same direction. The patient was chloroformed and reduction attempted with the heel in the axilla, but without success. On the 9th pulleys and counter-extending bands were obtained and adjusted. Chloroform was again administered, a drachm being poured upon a piece of lint about two inches square and held about three inches from his face, a towel being thrown over the head of the patient and hand of the operator, and which was removed from time to time to admit air. Some time elapsed before the muscles became relaxed, when the chloroform was removed. There was no stertorous breathing, choking, or struggling, nor was there occasion to use force to keep him down, as at the previous administration. There was, as there always is, congestion of the conjunctiva and vessels of the neck, but not as much, *certainly not more*, than when the chloroform was administered on the 6th. Reduction was being attempted when symptoms of asphyxia were noticed; the pulleys were instantly relaxed, the tongue drawn forward, and artificial respiration resorted to, but everything failed. No autopsy was made. The report of the case is signed by Surgeon H. A. Armstrong and Acting Ass't Surgeon H. W. Ducachet.

CASE 1268.—T. A. Leaning, Co. H, 76th New York, a patient in Eckington Hospital, was troubled with stricture of the urethra. An attempted examination by the catheter was so painful that chloroform was administered on a handkerchief, pains being taken that the patient had plenty of air by holding the handkerchief far enough away from the face. In a few minutes the rigidity of the muscles yielded, but only partly, and two or three stertorous respirations were taken. The chloroform was immediately suspended and the examination by the catheter commenced. The instrument had only been introduced to about the membranous urethra when an involuntary evacuation of both bladder and bowels took place; the patient at that moment ceased to breathe and his face grew purplish. The action of the heart could not be observed at this time, since the administrator

had not his finger on the pulse. On being immediately observed, no pulsation could be felt at the wrist nor observed on auscultation over the heart. The tongue was immediately pulled forward with a tenaculum, but as no respiration succeeded, Marshall Hall's ready method of artificial respiration was immediately commenced. The temporal artery was also instantly cut, but only a few drops of blood escaped. Respiration incomplete and obstructed by eructation; passive vomiting, with friction of the surface by the hand and by a stiff brush, and stimulating injections of ammonia and turpentine were kept up for over two hours with no favorable result, and the attempt at resuscitation was then given up. Acting Assistant Surgeon W. W. Keen, jr., who reports the case, remarks of the autopsy that "almost the only things strictly abnormal were the enormous congestion—probably passive—of the heart, fluidity of the blood, and the absence of rigor mortis."

CASE 1269.—Surgeon J. R. Weist, 1st Colored Troops, reports: "A death from chloroform occurred in hospital No. 12, Nashville, in 1862. The hospital was then under the charge of Surgeon Frederick Seymour, U. S. V. I supposed that he had reported the case. I cannot now obtain the name of the soldier, but there can be no mistake about it, as I administered the chloroform myself. The patient was a United States soldier (Irish), suffering from anal fistula, and the chloroform was carefully administered from a towel folded in the shape of a cone preparatory to an operation. The patient was in a well-ventilated room. About two drachms of the anæsthetic had been used, when death suddenly occurred without any warning. Autopsy revealed fatty degeneration of the heart. Nothing else abnormal found."

Considering the great number of cases in which chloroform was applied, principally during and after the exciting circumstances of a battle, when expedition was a matter of necessity, it is remarkable that not more cases of death from this agent have been recorded. With what justice the fatal issues in the cases here cited are chargeable to the anæsthetic the reader must judge for himself.

Deaths from Chloroform and Ether.—Two cases were reported. In one case, although the patient's condition would appear to have been favorable, no efforts at resuscitation seem to have been made; in the other case it is doubtful whether death was due to the severity of the injury or the anæsthetic:

CASE 1270.—Private Henry Jefferson, Co. E, 19th Colored Troops, aged 20 years; shot fracture of femur two inches below trochanter major, August 14, 1865; doing well until October 16th, when the pus became rusty. November 17th, Acting Assistant Surgeon H. Raphael, at the post hospital at Brownsville, Texas, administered an anæsthetic of two parts of ether and one part of chloroform with the intention of excising the ends of the bone; but after inhaling two minutes the patient began to sink pulse failed, spasms occurred, the head was drawn back and hands and feet were in a tremor; the sponge was removed, and the patient rallied; but upon re-administration spasms immediately returned, the pulse stopped, and the patient was dead.

CASE 1271.—Lieutenant Colonel J. C. Hodges, 44th Indiana, was injured on the railroad, September 27, 1864. The right femur was fractured and the soft parts lacerated; the left os calcis was also fractured; considerable hæmorrhage. At the patient's urgent request a mixture of chloroform and ether was administered. The pulse improved slightly, and amputation of the thigh was decided upon. Five minutes before the conclusion of the operation the breathing was noticed to be stertorous and soon intermitting, with flagging pulse. Artificial respiration was immediately resorted to by posture and by compression of chest at intervals, while the tongue was drawn forward by an assistant. This procedure gave much encouragement for a long time—indeed, for two hours the indications of returning vitality and consciousness seemed to depend entirely upon the vigorousness of the efforts at artificial respiration, but every effort failed to restore life.

Deaths from Ether.—Four cases were reported. In three cases death was probably due to the shock and the effects of the ether combined; in one an overdose was administered:

CASE 1272.—Captain *John Brennan*, Co. A, 16th Virginia, shot wound, right thigh, lower third, Weldon Railroad, October 27, 1864. Admitted into Harewood Hospital October 31st. The condition of the wound was good, but hæmorrhage occurred November 10th, from the popliteal artery, by which ten ounces of blood were lost. The artery was ligated in popliteal space, and the patient did well until November 21st, when the limb became œdematous. November 25th, hæmorrhage recurred to the amount of twelve ounces; it could not be controlled, and the limb was amputated; the patient died on the operating table from the shock and effects of ether. At the *post-mortem* no abnormities could be discovered, with the exception of slight venous congestion of the right lung and old adhesions of the left. The case is reported by Surgeon R. B. Bontecou, U. S. V.

CASE 1273.—An unknown soldier received, in 1862, a shot fracture of the condyle of the femur. The patient was stout and exhibited no symptom of exhaustion or severe shock; his heart acted with uniformity and strength; amputation was decided on and ether was administered, which produced insensibility in about ten minutes. As soon as the operation was begun the patient seemed to be regaining consciousness; but it required only a few seconds to restore complete anæsthesia. The assistant then removed the ether from the patient's face, but was ordered by the operating surgeon to renew the application. After one or two inspirations the patient ceased to breathe. The saw had not been applied nor the use of the knife been finished when death occurred. The case is reported by Dr. Walter Burnham.[1]

CASE 1274.—Private John Maxwell, Co. E, 159th New York, was wounded before Port Hudson, May 27, 1863, just below the knee, implicating the joint. He lay on the field of battle until midday of the 28th. His pulse was small and feeble and his

[1] BURNHAM (W.), (*Death from the Effects of Sulphuric Ether* [in an overdose.—ED.], in *The Boston Med. and Surg. Jour.*, 1870, Vol. VI, p. 377.

nervous system much prostrated. He was fed on beef tea and stimulants. He was brought to the field hospital, and three hours later ether was administered to him with a view of amputating the wounded leg. After being partially anæsthetized he was removed from where he had been lying and placed upon the operating table. More ether was then administered, and as soon as the patient appeared to be sufficiently narcotized a circular incision was made just above the knee joint. The assistant holding the pulse remarked that the circulation was failing, and efforts were immediately made to induce restoration of the vital energies by drawing out the tongue, throwing back the head, artificial respiration, and dashing of cold water. All was in vain, and the patient died May 28, 1863. The case is reported by Surgeon C. A. Robertson, 159th New York.

CASE 1275.—Private Henry S. Ware, Co. K, 38th New York, aged 23 years, was struck by a shell in the upper part of the right leg, at the battle of Williamsburg, May 5, 1862, for which injury the limb was removed on the field, at the middle third of the thigh. He was admitted into the general hospital at David's Island, New York Harbor, on June 15th, and came under the care of Acting Assistant Surgeon E. B. Root on June 26th, at which time his general condition was bad. He was suffering from diarrhœa and a very large bed-sore. The wound had nearly united but the bone was denuded. The constant discharge from the stump necessitated the removal of the necrosed bone. On October 9th the patient was placed under the influence of ether and an inch of bone removed with the chain saw, and then two inches of the bone with its involucrum. During the operation the femoral artery was divided, but not much blood was lost. Although it was found that more of the shaft was involved, further operative interference was deemed unnecessary. The patient was removed to his bed, when severe vomiting commenced which continued to the time of his death, seventy-two hours subsequently. The *post-mortem* examination showed all the viscera healthy. Surgeon S. W. Gross, U. S. V., ascribes the death to the effects of the ether superadded to the previous exhausted condition of the system. The constant vomiting and retching could not be arrested.

A few instances are recorded in which suspended animation was restored by energetic and prompt interference. The following two may serve as examples:

CASE 1276.—Private *A. Boyd*, Co. C, 38th Georgia, received a shot fracture of the right elbow joint, at Gettysburg, July 1, 1863, and was admitted to hospital at Frederick five days afterwards. Water dressings were applied until July 18th, when considerable œdema of the limb having become apparent, with redness about the joint, a resection of the injured parts was decided upon. The patient having been brought to the operating room, ether was administered by a Medical Cadet for fifteen or twenty minutes without producing anæsthesia, when from one and a half to two drachms of chloroform was added to the sponge and closely placed over the patient's mouth and nose. In the course of thirty or forty seconds stertorous breathing was produced, whereupon Assistant Surgeon R. F. Weir, U. S. A., in charge of the hospital, proceeded to operate and commenced the incisions. About this time, however, pulsation in the brachial artery was noticed to be running down rapidly, and the respiratory movements of the chest and abdomen were observed to have ceased, when one of the attending surgeons was instructed to examine the patient's tongue, and finding it had not fallen back, "Marshall Hall's" ready method was proposed and instantly applied. After this had been kept up for about half a minute and no respiratory effort had been observed, the operator immediately proceeded to open the larynx, when, after artificial respiration by means of compressing and relaxing the chest and abdominal walls for the period of about two minutes, natural breathing was re-established and pulsation of the radial artery could be felt. There was scarcely any hæmorrhage from the incision, and none, perhaps, entered the trachea. The edges of the wound were drawn together by adhesive straps. It not being thought proper to proceed with the operation of excision, the patient was returned to his ward and stimulants ordered to be given freely, also generous diet. He rested fairly and took broth very freely the next morning; pulse 130 and quite feeble; respiration quite easy. During the next night and for several days afterwards the patient had a daily chill, and there was considerable cough, with well marked capillary bronchitis throughout the whole extent of the left lung; tongue coated and brown; wound of elbow but little disposed to suppurate. These symptoms continued to grow worse, and subsequently there were several slight hæmorrhages from the incision over the olecranon process. During the last few days the patient's swallowing became very difficult, and beef tea and whiskey were administered by means of clysters. Death supervened on July 28, 1863. The *post-mortem* examination disclosed a small abscess on each side of the sternum, just beneath the pleura-costalis and about one and a half inches below the clavicles, and confirmed the existence of capillary bronchitis. The history of the case was furnished by Acting Assistant Surgeon W. S. Adams. The lower third of the injured humerus and a wet preparation of the upper portion of the trachea, the cricoid cartilage, and larnyx, showing the incision made, were contributed to the Museum by the operator, and constitute *Specimens* 3901 and 4080, respectively, of the *Surgical Section*.

CASE 1277.—Private S. R. Green, Co. A, 5th New Hampshire, was wounded in the leg, at Gettysburg, July 2, 1863, by a minié ball, which fractured the tibia and fibula. Amputation at the middle third of the leg was performed at a field hospital by Surgeon C. S. Wood, 66th New York, who made the following report: "Out of the hundreds of cases in which I have administered chloroform this is the only one accompanied by any unpleasant symptoms; here the patient sunk under its use, was apparently dead, and respiration and circulation both ceased. But by the continual use for some ten or fifteen minutes of Marshall Hall's ready method he was restored and the operation was proceeded with. The cause was evidently inattention on the part of the administrator." The patient subsequently died at the Seminary Hospital at Gettysburg on July 30, 1863.

The reports of the surgical operations of the war are very deficient in regard to the quantities of the anæsthetic used, the manner in which it was administered, the time required to produce insensibility, the period during which it was maintained, or the unfavorable symptoms following its application; the reports of the medical officers of the army after the war were somewhat fuller on these points; but to make them as complete as possible, the following order was issued in 1876 from the Surgeon General's Office:

WAR DEPARTMENT, SURGEON GENERAL'S OFFICE,
WASHINGTON, *October* 2, 1876.

CIRCULAR ORDERS. No. 2.

With a view of collecting precise data relative to the effects of chloroform and ether, Medical Officers are instructed to record, during the year 1877, the cases in which recourse is had to anæsthetics, noting the following particulars: Name and age of subject; nature of the anæsthetic; the quantity used in maintaining anæsthesia; the time required to induce complete insensibility; the time the anæsthetic influence was maintained; the mode of administration; whether vomiting, excitement, or great prostration was observed during or after the administration. These memoranda will be transcribed and returned on the Quarterly Reports of Wounded for March, June, September, and December, 1877.

BY ORDER OF THE SURGEON GENERAL:

C. H. CRANE,
Assistant Surgeon General, U. S. Army.

As the number of cases in which anæsthesia was employed during the year 1877 was limited, the order was continued in force by the following:

WAR DEPARTMENT, SURGEON GENERAL'S OFFICE,
WASHINGTON, *May* 20, 1878.

CIRCULAR ORDERS, No. 1.

Circular Orders No. 2, of October 2, 1876, from this Office, will be hereby continued in force until further orders. Medical Officers will render reports accordingly.

BY ORDER OF THE SURGEON GENERAL:

C. H. CRANE,
Assistant Surgeon General, U. S. Army.

The information thus obtained is here briefly given: The total number of cases since the close of the war, in 1865, in which anæsthesia was produced, is one thousand two hundred and ten (1,210). Of these chloroform was used in three hundred and fifty-five (355), ether in five hundred and eighty-seven (587), and ether and chloroform in two hundred and sixty-eight (268) cases. In the cases reported previous to the issue of *Circular Orders* No. 2, Surgeon General's Office, 1876, the data are, like those of the war, very incomplete, and we will therefore confine ourselves to the consideration of the cases reported since the issue of that order. They number five hundred and ninety-seven (597); in one hundred and fifty-seven (157), or 26.3 per cent. of these, chloroform; in one hundred and eight (108), or 18.1 per cent., chloroform and ether; and in three hundred and thirty-two (332), or 55.6 per cent., ether was administered. In three of the cases death was ascribed to the anæsthetic—to chloroform in one, to chloroform and ether in one, and to ether in the third.

The smallest quantity of chloroform used to induce anæsthesia was three-fourths of one drachm, of chloroform and ether one drachm, and of ether two drachms; the largest quantity of chloroform ninety-six drachms, of chloroform and ether one hundred and thirty drachms, and of ether two hundred and fifty-six drachms; the average amount of the agents used was chloroform eleven, chloroform and ether thirty-two, and ether fifty-one drachms. The average time in which insensibility was induced by chloroform was nine minutes, by ether and chloroform seventeen minutes, and by ether sixteen minutes, as shown in the following table:

TABLE CLXXIV.

Statement of Five Hundred and Ninety-seven Cases of the Employment of Anæsthetics, showing Quantities used, Time to induce Anæsthesia, and Period during which it was maintained.

ANÆSTHETIC AGENTS EMPLOYED.	CASES.	QUANTITIES USED.			TIME TO INDUCE ANÆSTHESIA.			ANÆSTHESIA SUSTAINED.		
		Small Quant.	Large Quant.	Average Quant.	Shortest Time.	Longest Time.	Average Time.	Shortest Time.	Longest Time.	Average Time.
		Drachm.	*Drachm.*	*Drachm.*	*Minutes.*	*Minutes.*	*Minutes.*	*Minutes.*	*Minutes.*	*Minutes.*
Chloroform	157	¾	96	11	½	35	9	1	180	22
Chloroform and Ether	108	1	130	32	1	60	17	1	130	26
Ether	332	2	256	51	1	55	16	1	235	26

The rapidity of the effects and the saving in quantity in the use of chloroform, so important to the field surgeon, especially after large battles, is at once apparent. There is hardly any difference in the average time required to produce anæsthesia by ether or by chloroform and ether.

Vomiting was recorded in twenty-three (23), or 14.6 per cent., of the one hundred and fifty-seven (157) cases of chloroform; in thirty-two (32), or 29.6 per cent., of the one hundred and eight (108) cases of chloroform and ether; and in ninety-eight (98), or 29.5 per cent., of the three hundred and thirty-two (332) cases of ether,—the relative frequency being nearly the same in the cases in which ether or ether and chloroform was used, and less in the cases of chloroform, as well as less copious:

TABLE CLXXV.

Statement showing the Frequency of Vomiting, Excitement, and Prostration in Five Hundred and Ninety-seven Cases of Anæsthesia.

ANÆSTHETIC AGENT EMPLOYED.	CASES.	VOMITING.			EXCITEMENT.				PROSTRATION.		
		None.	Slight.	Copious.	None.	Slight.	Marked.	Violent.	None.	Slight.	Marked.
Chloroform	157	134	20	3	113	23	9	12	136	11	10
Chloroform and Ether	108	76	25	7	68	24	10	6	95	11	2
Ether	332	234	83	15	202	85	31	14	295	24	13

Excitement was likewise reported less frequently in cases in which chloroform was administered than in those in which chloroform and ether or ether was used, the percentages being 28.0 in chloroform, 37.0 in chloroform and ether, and 39.1 in ether; but, as the figures in the table indicate, it seems to have been somewhat more violent in the cases of chloroform narcosis, although in one case in which ether was employed the excitement was so intense that the use of the anæsthetic was abandoned and the operation completed without anæsthesia. Prostration was reported in twenty-one, or 13.3 per cent., of the cases of chloroform; in thirteen, or 12.0 per cent., of the cases of chloroform and ether; and in thirty-seven, or 11.1 per cent., of the cases of ether.

In four of the one hundred and fifty-seven cases in which chloroform was used slight disturbance of respiration was noted, and in two cases respiration ceased and the pulse stopped, but life was restored after prolonged efforts. Pulse and respiration were likewise suspended in two instances in which ether and chloroform, and in one in which ether alone, had been used; they also were brought back to consciousness. In three cases death was ascribed to the anæsthetic. A case of death from chloroform is reported by Assistant Surgeon R. Barrett, U. S. A.:

CASE 1278.—Private A. L. Bruce, Co. G, 13th Infantry, aged 26 years, suffered from bleeding internal piles, and deriving no benefit from a palliative treatment it was decided to relieve him by operation. After abstaining from solid food for sixteen hours the patient was, on August 28, 1877, placed on the operating table and the administration of chloroform was commenced. The inhaler used was a towel folded cone-shaped, with an inch aperture at the apex. Fearing that this opening was not sufficiently large to admit of the free access of atmospheric air, the inhalation was discontinued and the opening enlarged to twice its former size. The inhalation was then resumed, the patient at this time lying on the table and quietly observing the operations going on around him. I am thus minute as I wish to show that the patient was perfectly conscious when the second inhalation began. He took the anæsthetic kindly for about a minute, when he suddenly sat upright and asked if his piles were out. I replied "No, lie down;" he said "All right doctor, I have the utmost confidence in you." His head had hardly touched the table when his radial pulse ceased and his face became intensely congested; his breathing was stertorous and a large quantity of froth appeared on his lips. I directed the attendants to seize his heels and hold him up, head down, at the same time

applying aqua ammonia to the nostrils. His respiration was now reduced to an occasional gasp, and finding the Nélaton position of no benefit I had him laid on the table, and drawing forward his tongue with a forceps introduced a large gum catheter into the trachea and gently blew air into the lungs; this was repeated several times, the air being forced out after each inflation by pressing on the thorax. While attempting artificial respiration I ordered an enema of whiskey, which was retained, but was immediately followed by a copious discharge of urine. This was the last act of the patient's life, for he was now dead, and I reluctantly discontinued my efforts to revive him. I have estimated the quantity of chloroform used as about two drachms. Death no doubt occurred from paralysis of the heart, as there was no evidence of a pulse after it first ceased at the wrist. After the patient's death I learned that he had stated that he had heart disease and expected to die under the operation.

Assistant Surgeon C. E. Price reports a case of death from the administration of ether; the case was hopeless before the operation was begun:

Case 1279.—A. J. Moore, aged 50 years, suffered for about six years from the results of a contusion of the knee. The joint became swollen and painful, and an examination in May, 1878, showed that the bone had become diseased. Amputation or resection was advised, but the patient refused to be operated upon, and gradually became worse until July 11th, when he finally consented to an amputation. He was then put on a generous diet with stimulants. However, he grew rapidly worse. The urine had only a trace of albumen, but there was œdema of the lungs with evidence of great effusion in the pleural cavity. His breath began to be labored, and there were large, coarse, moist rales in both lungs, while the effusion almost destroyed all movement in the left lung and impaired that of the right. He became greatly alarmed, as in two or three coughing spells he was nearly strangled to death. He now begged me to operate, and said he was sure to die very soon if I did not. When I explained the dangers of the operation he said he knew it all, but that it gave him a possibility of life. Having no assistant of any kind, I called upon Lieut. Halloran, 12th Infantry, who had on several occasions attended to the administration of an anæsthetic for me. I read to Lieutenant Halloran and gave him to study the instructions as given in Ashhurst's and Erichsen's Surgery, and explained to him the importance of closely watching the effects of the anæsthetic. I had but six ounces of ether (Squibb's), so I took the bottle of chloroform for use in case the ether should prove insufficient. With Lieutenant Halloran to attend to the anæsthetic and two soldiers for assistants I began. At first I attended to the anæsthetic myself. After a few breaths of the ether I said: "Moore, do you feel it?" He said: "A little." A few more breaths and he said: "Wait a minute and give me a rest;" I replied "all right," but kept along with the ether. After a few moments more I gave the sponge to Lieutenant Halloran and began applying an Esmarch's bandage. I had wrapped it up to the lower part of the swelling about the knee when I looked up and said to Lieutenant Halloran "take away the sponge," and noticed that his breath had stopped. Lieutenant Halloran replied: "His pulse is good," but by the time I felt it it had disappeared. I instituted artificial respiration at once, applied nitrite of amyl to his nostril, and injected ammonia into a vein of the arm. I kept up artificial respiration after Sylvester's method for three-quarters of an hour, but it was of no avail. In the chest a large effusion was found in the pleural cavity, with stringy pus and bands of adhesion in many places. The upper and middle portions of the left lung were thickly filled with points of caseous deposit, and in many of these spots were deposits which were as hard as and seemed to be solid limestones. The right side of the heart was dilated and nearly full of clotted blood; the left side was nearly empty.

The details of a case in which first ether and subsequently chloroform were administered are given by Assistant Surgeon P. J. A. Cleary, U. S. A.:[1]

Case 1280.—Private H. D. Bradfield, Co. H, 19th Infantry, aged about 33 years, large and robust, addicted to liquor, was admitted to hospital December 3, 1878, suffering with an injury of the middle finger, right hand, resulting in gangrene of the second and third phalanges, and in consequence it was decided to amputate at the metacarpal articulation. For this purpose a mixture of equal parts of ether fortior and chloroform was administered. About ten minutes previously two ounces of whiskey were given. I examined his heart and found it normal in every respect. The anæsthetic was administered on a piece of lint, covered with a small towel, held square in contradistinction to cone-shaped. I personally administered the mixture while the steward observed his pulse. The cloth was held so as to allow a free admixture of air. He inhaled freely. About two drachms were first poured on the cloth, but had no apparent effect. Shortly after about the same quantity was poured on; he observed that "he did not feel it." After a time about the same quantity was again poured on, and, as I turned to look at some instruments, he requested me not to begin yet to cut him. A further quantity was now poured on the cloth, when he began to laugh; this was followed by attempts to articulate, then, as is common, by strong gesticulations of his arms, to stop which the steward forcibly pressed down one arm, holding him by the wrist, while an attendant did likewise with the other. He was now passing to a state of unconsciousness, and in reply to my inquiry the steward said he could not feel the pulse, but added that his arm was somewhat twisted, which prevented his perceiving the pulse. I therefore felt for the pulse at the other wrist, but could not perceive it. Just as I felt, the muscles of his arm and neck, which had been strongly in action, suddenly relaxed; his breathing, however, was very good and such as would in no wise have attracted attention. At once I removed the anæsthetic and dashed some cold water in his face. The pulse did not return. He continued to breathe freely for a little time longer, then his breathing became labored, and then suddenly stopped. The action of the heart had previously stopped, and the man was dead. I will add that everything I ever heard of, saw, or read, appropriate for such cases, was done, but to no effect. The mixture consisted of chloroform and ether fortior; amount used exactly one ounce; time in using it, fifteen minutes. Cause of death, paralysis of the heart. Of the entire amount used one-half only was chloroform, *i. e.*, half an ounce. Of this amount a large proportion was wasted over the cloth and which he never inhaled: the inhalation of the remainder occupied fully fifteen minutes.

[1] The case has been reported in the *Philadelphia Medical Times*, 1879, Volume IX, page 280.

CHAPTER XIV.

THE MEDICAL STAFF AND MATERIA CHIRURGICA.

Previous to the outbreak of the rebellion the regular army numbered one thousand one hundred and seventeen (1,117) commissioned officers and eleven thousand nine hundred and seven (11,907) enlisted men. The Medical Department was composed of one Surgeon General with the rank of Colonel; thirty Surgeons with the rank of Major, and eighty-four Assistant Surgeons holding for the first five years the rank of 1st Lieutenant, and subsequent to that period, until promotion to Surgeon, the rank of Captain. The officers of the Medical Department formed a portion of the General Staff of the army; were not permanently attached to any regiment or command, but were subject to duty wherever their services were needed. Experience had demonstrated this system to be the best for the necessities of an army widely scattered over an immense area of territory, serving in commands of less than regimental strength, while it possessed the advantage of increasing the efficiency and value of the medical force in a professional point of view.

At the beginning of hostilities, in 1861, large forces of State troops, or militia, responded to the several proclamations of the President calling for aid in suppressing the rebellion. Each regiment was provided with a Surgeon and an Assistant Surgeon commissioned by the States in which the troops had been enlisted. These officers were borne on the muster-rolls and permanently attached to the regimental organization, being seldom detached except for urgent reasons.

During the early military operations the administrative duties pertaining to the Medical Department were performed by officers of the regular medical staff, detailed for the purpose, or by volunteer Surgeons appointed as Medical Directors of Divisions, as allowed by the President's proclamation of May 3, 1861.

On the 22d of July, 1861, Congress passed an act authorizing the President to raise a force of volunteers, not exceeding 500,000, and prescribing the organization of this levy into divisions of three or more brigades, and that "each brigade shall be composed of five or more regiments, and shall have one Brigadier General, two Aids-de-Camp, one Assistant Adjutant General with the rank of Captain; *one Surgeon;* one Assistant Quartermaster, and one Commissary of Subsistence." The Surgeons authorized by this act were known as Brigade Surgeons, and were borne as such on the official army registers of September, 1861, and January, 1862; they held the rank of Major.

The duties, prerogatives, and responsibilities of Brigade Surgeons being somewhat vaguely defined, the following bill was passed by Congress on July 2, 1862: "From and after the passage of this act Brigade Surgeons shall be known and designated as Surgeons

of Volunteers, and shall be attached to the general medical staff under the direction of the Surgeon General; and hereafter such appointments for the medical service of the army shall be appointed Surgeons of Volunteers."

The Brigade Surgeons, or Surgeons of Volunteers as they were henceforth called, were assimilated to those of the regular staff, holding equal rank with the latter under commissions conferred by the President and confirmed by the Senate. They became eligible to all the duties and prerogatives pertaining to the medical officers of the army, whether in the field as Directors of Armies, Corps, or Departments, or in charge of hospitals, etc. From time to time, by acts of Congress, additions were made to the regular and volunteer corps, and such changes effected as were necessarily demanded. The act of April 16, 1862, was one of the most important of these acts, wherein the rank of Brigadier General was conferred upon the Surgeon General. Provisions were also made in this act for an Assistant Surgeon General and a Medical Inspector General, both with the rank, pay, and emoluments of Colonel of Cavalry, and for eight Medical Inspectors with the rank, pay, and emoluments of Lieutenant Colonel of Cavalry, also for Medical Purveyors and Medical Cadets. The text of the act is here inserted:

"AN ACT TO REORGANIZE AND INCREASE THE EFFICIENCY OF THE MEDICAL DEPARTMENT OF THE ARMY.

"*Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled*, That there shall be added to the present medical corps of the army ten Surgeons and ten Assistant Surgeons, to be promoted and appointed under existing laws; twenty medical cadets, and as many hospital stewards as the Surgeon General may consider necessary for the public service, and that their pay and that of all hospital stewards in the volunteer, as well as the regular service, shall be thirty dollars per month, to be computed from the passage of this act. And all medical cadets in the service shall, in addition to their pay, receive one ration per day, either in kind or commutation.

"SEC. 2. *And be it further enacted*, That the Surgeon General to be appointed under this act shall have the rank, pay, and emoluments of a Brigadier General. There shall be one Assistant Surgeon General and one Medical Inspector General of Hospitals, each with the rank, pay, and emoluments of a Colonel of Cavalry, and the Medical Inspector General shall have, under the direction of the Surgeon General, the supervision of all that relates to the sanitary condition of the army, whether in transports, quarters, or camps, and of the hygiene, police, discipline, and efficiency of field and general hospitals, under such regulations as may hereafter be established.

"SEC. 3. *And be it further enacted*, That there shall be eight Medical Inspectors, with the rank, pay, and emoluments each of a Lieutenant Colonel of Cavalry, and who shall be charged with the duty of inspecting the sanitary condition of transports, quarters, and camps, of field and general hospitals, and who shall report to the Medical Inspector General, under such regulations as may be hereafter established, all circumstances relating to the sanitary condition and wants of troops and of hospitals, and to the skill, efficiency, and good conduct of the officers and attendants connected with the medical department.

"SEC. 4. *And be it further enacted*, That the Surgeon General, the Assistant Surgeon General, Medical Inspector General, and medical inspectors, shall, immediately after the passage of this act, be appointed by the President, by and with the advice and consent of the Senate, by selection from the medical corps of the army, or from the surgeons in the volunteer service, without regard to their rank when so selected, but with sole regard to qualifications.

"SEC. 5. *And be it further enacted*, That medical purveyors shall be charged, under the direction of the Surgeon General, with the selection and purchase of all medical supplies, including new standard preparations, and of all books, instruments, hospital stores, furniture, and other articles required for the sick and wounded of the army. In all cases of emergency they may provide such additional accommodations for the sick and wounded of the army, and may transport such medical supplies as circumstances may render necessary, under such regulations as may hereafter be established, and shall make prompt and immediate issues upon all special requisitions

made upon them under such circumstances by medical officers; and the special requisitions shall consist simply of a list of the articles required, the qualities required, dated, and signed by the medical officers requiring them.

"SEC. 6. *And be it further enacted*, That whenever the Inspector General, or any of the medical inspectors, shall report an officer of the medical corps as disqualified, by age or otherwise, for promotion to a higher grade, or unfitted for the performance of his professional duties, he shall be reported by the Surgeon General for examination, to a medical board, as provided by the seventeenth section of the act approved August third, eighteen hundred and sixty-one.

"SEC. 7. *And be it further enacted*, That the provisions of this act shall continue and be in force during the existence of the present rebellion and no longer: *Provided*, however, that, when this act shall expire, all officers who shall have been promoted from the medical staff of the army under this act shall retain their respective rank in the army, with such promotion as they would have been entitled to."

Approved April 16, 1862.

Beside the medical officers of the regular and volunteer staff, and the medical officers of regiments, there was a class designated as Acting Assistant Surgeons, who were private physicians, uncommissioned, serving under contract to do duty with the forces in the field or in general hospitals. This class was very large and embraced in its number some of the most eminent surgeons and physicians of the country. The Medical Cadets were generally young men, students of medicine, who were assigned to duty in general hospitals as dressers and assistants. The Medical Department was still further increased by a number of Hospital Stewards, who were enlisted as needed, and who performed the duties of druggists, clerks, and storekeepers.

During the years of the war the organization of the Regular Staff had been increased so as to number one Surgeon General, one Assistant Surgeon General, one Medical Inspector General, sixteen Medical Inspectors, and one hundred and seventy Surgeons and Assistant Surgeons; there had been appointed five hundred and forty-seven (547) Surgeons and Assistant Surgeons of Volunteers; there were mustered into service between April, 1861, and the close of the war, two thousand one hundred and nine (2,109) regimental Surgeons, three thousand eight hundred and eighty-two (3,882) regimental Assistant Surgeons. During the same period there were employed eighty-five (85) Acting Staff Surgeons and five thousand five hundred and thirty-two Acting Assistant Surgeons.[1]

To the fidelity and efficiency of this vast body of professional men the Surgeon General, in his annual report of 1865, bears the following well-deserved tribute: "I desire to bear testimony to the ability, courage, and zeal manifested throughout the war by the officers of the Medical Department under all circumstances and upon all occasions. With hardly an exception they have been actuated by the highest motives of national and professional pride, and the number who have been killed or wounded bear honorable testimony to their devotion and duty on the field of battle."

The following record of casualties of the Regular and Volunteer Staff during the war shows well for the honor of those who are erroneously supposed to escape the dangers and chances of war: "Thirty-two (32) were killed in battle, or by guerillas or partizans, and nine (9) by accidents; eighty-three (83) were wounded in action, of whom ten (10) died; four (4) died in rebel prisons, seven (7) of yellow fever, three (3) of cholera, and two hundred and seventy-one (271) of other diseases, most of which were incidental to camp life or the result of exposure in the field."[2]

[1] BROWN (H. E.), *The Medical Department of the United States Army from* 1775 *to* 1873, Washington, Surgeon General's Office, 1873, p. 245.
[2] BROWN (H. E.), (*loc. cit.*), p. 246.

Of the amount of labor performed by the Medical Staff during the war some idea may be obtained when it is stated that 5,825,480 cases of wounds and disease occurred among the white troops and 629,354 cases among the colored troops.[1]

"The cost of maintaining the Medical Department formed no small portion of the total expenses of the war, and it is a matter of just pride that it can be said that the medical disbursing officers performed their duties faithfully and honestly, and that the immense quantities of medical supplies distributed all over the country were almost without exception properly accounted for. The expenditures on behalf of the Medical Department to the close of each fiscal year, on the 30th of June, from 1861 to 1866, were as follows:

1861	$194,126.77
1862	2,371,113.19
1863	11,594,650.35
1864	11,025,791.33
1865	19,328,499.23
1866	2,837,801.37

making a total of $47,351,982.24 expended during the war (exclusive of salaries of commissioned officers) for the benefit of the sick and wounded soldiers of the nation."[2]

After the organization of the forces raised for the suppression of the rebellion was perfected, the medical service in the field was based upon an independent hospital and ambulance establishment for each division of three brigades. The *personnel* of the division hospital consisted of a Surgeon in charge, with an Assistant Surgeon as executive officer and a second Assistant Surgeon as recorder, an operating staff of three Surgeons aided by three Assistant Surgeons, and the requisite number of nurses and attendants.

The division ambulance train was commanded by a First Lieutenant of the line, assisted by a Second Lieutenant for each brigade. The enlisted men detailed for ambulance duty were a sergeant for each regiment, three privates for each ambulance, and one private for each wagon. The ambulance train consisted of from one to three ambulances for each regiment, squadron, or battery, a medicine wagon for each brigade, and two or more supply wagons. The hospital and ambulance train were under the control of the Surgeon-in-Chief of the Division. The division hospitals were usually located just out of range of artillery fire. Sometimes three or more division hospitals were consolidated under the orders of a Corps Medical Director, who was assisted by his Medical Inspector, Quartermaster, Commissary, and chief ambulance officer.

The medical officers not employed at field hospitals accompanied their regiments and established temporary depots as near as practicable to the line of battle.

As soon as possible after every engagement the wounded were transferred from the division or corps hospitals to the base or general hospitals, which at one time numbered 205; these were under the charge and command of the Regular or Volunteer Staff, assisted by Acting Assistant Surgeons, Medical Cadets, and officers of the 2d Battalion of the Veteran Reserve Corps.

The following extracts of reports are presented to show the system of the medical organization in one of the corps of the Army of the Potomac. The reports, which give in detail the specific duties of each class of officers, were made in accordance with the following circular letter of Surgeon T. A. McParlin, Medical Director of the Army of the Potomac:

[1] BROWN (H. E.), *The Medical Department of the United States Army from 1775 to 1873*, Washington, Surgeon General's Office, 1873, p. 246.

"HEADQUARTERS ARMY OF THE POTOMAC,
"MEDICAL DIRECTOR'S OFFICE,
"*September* 28, 1864.

"Surgeon J. J. MILHAU, U. S. Army,
"*Medical Director Fifth Army Corps.*

"DOCTOR: You will require from one of each of the following named officers a detailed written report of their duties, both sedentary and active, the reports they make and receive, their duties and positions before and after engagements and on the march:

1. Medical Director of Corps.
2. Medical Inspector of Corps.
3. Surgeon-in-Chief of Division.
4. Surgeon-in-Chief of Brigade.
5. Surgeon in charge of Division Hospital.
6. Recorder of Division Hospital.
7. Attending or Prescribing Surgeon of Division.
8. Operating Surgeon.
9. Surgeon of Regiment.
10. Assistant Surgeon of Regiment.
11. Division Hospital Commissary.
12. Chief Ambulance Officer of Corps.
13. Chief Ambulance Officer of Division.
14. Ambulance Officer of Brigade, who will also specify the duties of the non-commissioned officers and privates under him. The reports when rendered you will forward to this office.

"Very respectfully, your obedient servant,
(Signed) "THOMAS A. McPARLIN,
"*Surgeon U. S. Army and Medical Director Army of Potomac.*"

The responses to this circular were collected by Surgeon J. J. Milhau, U. S. A., and by him transmitted to the Medical Director, T. A. McParlin. Omitting the official verbiage and forms the substance of the reports is here given:

"*Duties of the Medical Director of a Corps:* The Medical Director of a Corps is the head of the Medical and Ambulance Departments of the corps, and he is held responsible by the Corps Commander that they be properly and effectively managed under all circumstances. It is therefore impossible to specify definitely his duties in every case. He should possess the confidence of his Commander and ask for instruction in all cases of doubt. He should have an office and at least two clerks, of whom one should be a Hospital Steward. The following books should be kept, viz: 1st, a Register of all Medical Officers and regular Hospital Stewards belonging to the Corps; 2d, an Endorsement Book; 3d, a Record of Certificates of Death, and action thereon; 4th, a Letter and Order Book; 5th, a Blotter, in which are checked off the regular requisitions and Monthly Reports of Sick and Wounded as received; 6th, a Manifold Writer. The following regular reports are received: 1st, Daily Report of the Medical Inspector of the Corps; 2d, the Weekly Report of Sick and Wounded; 3d, the Weekly Report of the Ambulance Corps (in duplicate); 4th, the Weekly Report of Brandy and Whiskey received, issued, etc., from each Brigade and from each Hospital; 5th, the Monthly Returns of Medical Officers from Divisions and Brigades; 6th, the Monthly Returns of Hospital Stewards, U. S. A.; 7th, the Monthly Returns of Ambulance Officers (in duplicate); 8th, Statement of Hospital Fund from each Hospital. After engagements are to be transmitted to the Medical Director of the Army: 1st, Nominal Lists of Wounded, for transmittal; 2d, Classified Returns of Injuries and Wounds (in duplicate); 3d, Aggregate Mean Strength of Command (per regiment); a Report of the Operations of the Ambulance Corps. The following Consolidated Reports for the Corps are made at stated periods to the Medical Director of the Army: 1, Weekly Report of Sick and Wounded; 2d, Monthly Return of Medical Officers; 3d, Monthly Return of Hospital Stewards, U. S. A.; 4th, Statement of Balance due Hospital Fund; 5th, Record of Certificates of Disability, and action thereon. All other reports are simply transmitted without consolidation, including certificates of death. The following papers are referred, by order of the Corps Com-

mander, to the Medical Director for approval, recommendation, expression of opinion or disapproval, viz: All tenders of resignations on account of disability; all applications for leaves of absence; all certificates of disability for discharge, and invalid rolls when doubtful; all recommendations and complaints referring to the Medical and Ambulance Departments or affecting the health and well being of the troops; all applications for leave of absence or resignation of Medical or Ambulance Officers—in fact, all papers relating to the Medical Department are referred to the Medical Director prior to the action of the General Commanding. The following papers require to be examined and acted upon by the Medical Director: All requisitions for Medical and Hospital Supplies, and all requisitions and estimates for supplies for the Ambulance Corps. Written circulars and instructions from the Medical Director of the Army and from the Surgeon General should either in whole or part be promptly published to the Surgeons-in-Chief of Divisions and Surgeons-in-Chief of separate commands. The health and welfare of the troops, as well as the comfort and proper care of the sick and wounded, should receive the unceasing attention of the Medical Director. It therefore becomes his duty to ascertain, through the Medical Inspector, the Surgeons-in-Chief of Divisions, and, from his own observation, the existence of irregularities and of deficiencies in the hospitals or in the command, and he must issue the necessary instructions to have the one corrected and the other supplied. In matters of defective police, bad drainage, unhealthy camp grounds, insufficient shelter, improper or damaged food, etc., etc., he should first call the attention of the Medical Officers to the fact and suggest remedies; but if these suggestions be not promptly attended to, a written report with recommendations should be made without delay to the Corps Commander. Special attention must be given to the keeping up of supplies, both medical and hospital. Circulars should be issued from time to time, giving information to the medical officers as to what articles can be obtained, specifying the manner of obtaining them. The Ambulance Corps being under the direction of the Medical Director, the ambulances and everything connected with them claim a full share of his attention. In conjunction with the Chief Ambulance Officer he must therefore see that nothing is neglected to render them efficient in every respect and the intention of the law be carried out. The Surgeons-in-Chief of Divisions look to the Medical Director for orders, instructions, and suggestions in reference to the fitting up of the different hospitals; he should therefore instruct them as to the number of tents to be pitched, and as to whether it is desirable to construct fire-places, erect bunks, dig wells, etc., etc. As a general rule, verbal orders will be sufficient. When a movement is ordered, the Medical Director should ask for instructions in reference to the sending off of sick and wounded, the breaking up of the hospitals, the number of ambulances and wagons allowed to march with the troops, and the number to be sent to the rear, and on receiving them will give the necessary orders in writing, specifying the number of tents and flies to be carried, as well as the amount of hospital supplies, medical stores, clothing, and rations, and directing the Surgeons-in-Chief of Divisions to see that the "hard bread" is put up in the ambulance boxes, and the field companions and hospital knapsacks are filled. Orders should be given to the Chief Ambulance Officer in reference to the position of the stretcher bearers; as a general rule they should all march with their commands, with stretchers. When only a limited number of ambulances accompany the troops, all the stretchers should go to the front strapped on the ambulances. Orders should be given to have the water-kegs filled. On the march the Medical Director accompanies the Staff, acquainting himself as far as practicable with the nature of the country passed over, the general direction and condition of the roads, the position of the houses, streams, woods, etc., etc. This knowledge will materially assist him in the selection of hospital sites. When an engagement commences the Medical Director should ascertain the position of the troops, and should immediately communicate with the Surgeons-in-Chief of Divisions, directing the establishment of field depots for the wounded at such points as will be most convenient for collecting them and where the ambulances can come up. In locating these depots special care must be taken to have them as near the line of troops as possible, so as to diminish the distance of stretcher transportation. Ravines and woods should be taken advantage of as a protection against the enemy's fire; if necessary, a breastwork can be thrown up by the attendants. An occasional bullet or an occasional shell is not sufficient to warrant Medical Officers in leaving their posts. If practicable, the Medical Director should himself visit and inspect these depots, and give orders that will insure the object of their establishment; he should also consult with the Chief Ambulance Officer as to the best roads, everything considered, to be taken by the ambulances. Should the enemy fall back these depots should be removed

farther to the front; should our own troops yield the ground, the depots must be moved farther to the rear. The moment the number of wounded warrants the establishment of Division Hospitals the Corps Commander should be consulted as to the locality of these hospitals, in a military point of view. The Medical Director then selects the site himself, or designates some one to do it in his name. Orders should be immediately given to the Surgeons-in-Chief of Divisions and to the Chief Ambulance Officer, designating the locality chosen. Should a lull occur in the firing or the enemy be driven back, orders must be immediately given to advance the field depots and to take all the available ambulances to the front to pick up the wounded as rapidly as possible, and to convey them to the hospitals. During an engagement the duty devolving upon the Medical Director of a Corps to select a site for the different hospitals of the Corps is not always an easy one. As a general rule they should be placed near the most practicable roads, in rear of the centre of the troops, and sufficiently to the rear to be out of the ordinary range of the enemy's guns; suitable ground, good water, and plenty of fuel must of course decide the choice of locality. During the action the Medical Director must keep himself thoroughly acquainted with the movements of the troops and act accordingly. The Corps may take up a new position with a different front; sometimes a part or even the whole of a Corps may meet a superior force and be repulsed; under such circumstances the Medical Director should be ready to act promptly, and to transfer his wounded to a safer locality. Should the Corps Commander be present he will advise his Medical Director of the state of affairs and give orders in reference to the removal of the hospitals. There are times, however, in which the Director is called upon to act upon his own responsibility. Should it become necessary to leave the wounded in hospitals in the hands of the enemy, the Medical Director will see that they are properly sheltered, that a sufficient number of Medical Officers, Hospital Stewards, and attendants remain with them, and that an ample supply of medical and hospital stores, dressings, and provisions be left for their comfort. After an engagement, the Medical Director of the Army should be communicated with as to the means of transportation for the wounded to General Hospital; he should be informed of the number and of the time at which they will be ready for such transit; on receiving instructions the necessary orders are given. The Medical Inspector generally attends to the shipment of wounded. During action the duties of a Medical Director require his presence at Corps Headquarters, where he can be found, and where he can obtain the earliest information and receive orders and reports. As a general rule, therefore, he cannot stop to operate during an engagement; he should remember that he is responsible for all the wounded, and that there are occasions in which the delay of half an hour will result in the loss of his hospitals. The Corps Commander should be kept informed of the operations of the Department both during and after engagements, and should always be consulted in matters of importance. As it is necessary for the Medical Director to visit his hospitals and field depots from time to time, he should always leave a competent Medical Officer at headquarters to represent him. When practicable, the hospitals of the different Divisions should be located near together—each one, however, to be kept perfectly independent and distinct in its management. This will much facilitate the operations of the Ambulance and Medical Departments, enabling the divisions to assist each other in taking care of the wounded. For instance, should one Division suffer more than another, an operating staff, or more if necessary, with the Autenrieth wagon, can be ordered to the suffering Division; again, should one Division be deficient in shelter or supplies, they can be obtained from the other Divisions; another advantage is the facility given for inspection, and for giving instruction, and in distributing the wounded as they come in; for instance, all available ambulances are used when wanted, without reference to their Divisions. An ambulance reaches the hospital containing wounded of different Divisions, no difficulty is experienced in distributing them, each to his own Division Hospital, thus enabling them to be treated by their own Medical Officers and to be registered in their own Divisions. Again, in sending off the wounded to General Hospital, the loading of the wagons will be much facilitated and a corps train readily found. When avoidable, the wounded should not be sent off from the field Division Hospital until they have been operated upon, properly dressed, fed, and have obtained some rest, and have somewhat recovered from the shock. In sending sick and wounded off to General Hospital the Corps Director gives the necessary orders to have the wagons or cars properly bedded with brush or hay, specifies the number of rations to be taken, and the number of Medical Officers, Stewards, and attendants that should accompany the train, giving any instructions that he may deem important in reference to the roads, camping, etc. When the troops

remain in camp some time, it will be found convenient to have near each Division a few ambulances, with horses hitched up ready to convey a patient to the hospital. These are known in the Corps as picket ambulances, and are relieved every twelve hours. At this post there should be a medicine wagon, under the charge of a Steward, to issue medicines to the regimental Surgeons. The post should be marked by an ambulance guidon; this wagon to be relieved as often as emptied. As a large number of stretchers and lanterns are always broken or lost during an engagement, orders should be given after an action to have the deficiencies supplied as early as possible.

"*Duties of the Medical Inspector of a Corps:* A Medical Inspector of a Corps has but few specific duties assigned to him, and these, with one exception, are such as the Medical Director may direct to facilitate the management of the Medical Department and keep him informed of the deficiencies which need correcting and errors that should be rectified; as his relative position to the Medical Director is analogous to that occupied by an Assistant Adjutant General to his Commanding General, any authority he may exercise in the discharge of duty is entirely delegated power. The only reports made to him are the daily morning reports of each hospital from which the Corps report is made. A monthly report of the inspection of troops has been used, but since that has been abandoned reports, not in tabular form, have been made of the condition of the troops only to the Medical Director, calling his attention to any violation of sanitary rules that may have been observed. Previous to an engagement, or march, he sees that the direction of his superior officers relative to the proper disposition of the flying hospital and medicine wagons are obeyed, and that they are in readiness to accompany the troops. The principal duty devolved upon him during an engagement has been to represent the Medical Director at the hospitals, to see that the men are properly provided for, and when instructed to send wounded to the rear to assist the Chief Ambulance Officer in the proper apportioning of the means of transportation, to make the detail of Medical Officers and attendants to accompany the train, and ascertain that they are provided with stimulants and other essentials to render the patients confided to them as comfortable as possible.

"*Duties of the Surgeon-in-Chief of a Division:* 1. The Surgeon-in-Chief of a Division promulgates to Surgeons-in-Chief of Brigades all orders, circulars, and communications that are received from the Medical Director of the Corps, also all orders, circulars, and communications pertaining to the Medical Department that emanate from Division Headquarters. 2. He receives all reports that are made by the Surgeons-in-Chief of Brigades and consolidates them before forwarding them to the Medical Director of the Corps, except the 'Monthly Report of Sick and Wounded' furnished by the regimental Surgeons, and the weekly report of 'Brandy and Whiskey' furnished by the Surgeons-in-Chief of Brigades: these are forwarded without any action from him. The only reports made directly by him are the 'Monthly Return of Medical Officers' of the Division, which he forwards to the Medical Director of the Corps, and the Personal Report to the Surgeon General from the post at which he is serving. 3. All requisitions for medicines and hospital supplies, made by the Surgeons-in-Chief of Brigades, are received by him and forwarded to the Medical Director of the Corps, without any action from him except 'Special Requisitions,' which are either approved or disapproved before being forwarded. 4. All applications for leave of absence and resignation on Surgeon's certificate, and all Certificates of Disability for discharge of enlisted men, are forwarded from their regiments through the regular military channel and referred to the Surgeon-in-Chief of the Division by the Assistant Adjutant General of the Division; each case is personally examined by the Surgeon-in-Chief and the action indorsed on the official paper. Applications for leave of absence of Medical Officers are referred to the Surgeon-in-Chief by the Assistant Adjutant General for his action. 5. All details of Medical Officers and enlisted men for duty at Division Hospitals are made by the Assistant Adjutant General, to whom the names, rank, regiment, and company are furnished by the Surgeon-in-Chief. 6. The Surgeon-in-Chief of a Division has no official relation with any Staff Officers except the Assistant Adjutant General. 7. A detail of one Medical Officer as 'Officer of the Day' is made each day by the Surgeon-in-Chief, with instructions to visit each regiment of the Division and inspect carefully its hygienic and sanitary conditions, also to visit the Division Hospital and see that proper attention is given to cleanliness and to the comfort of the patients; examine the cooking and whether the attendants perform their duties faithfully. A written report to be furnished of these investigations. 8. Before an engagement the detail for the 'Field Hospital' is announced by the Surgeon-in-Chief of the Division: the Surgeon in charge of the Division Hospital remains in charge and has control of all the shelter; the officer detailed

as Hospital Commissary provides the food; the records are kept by a Hospital Steward, U. S. A. Three (3) Surgeons are detailed as operators, and three (3) Medical Officers are assigned to each operator as Assistants. One Cook, two Nurses, and one Hospital Steward are taken from each regiment for the 'Field Hospital.' 9. The Medical Officers who remain on the field at the time of and after an engagement are instructed to form their depots and locate them by Brigades, and are to select their positions in compliance with instructions of 'Circular' from Headquarters, Army of the Potomac, Medical Director's Office, dated October 30, 1862, and to examine each man before he is put in an ambulance. 10. The position of a Surgeon-in-Chief of a Division during an engagement is, first to locate the 'Field Hospital' and see that the details are properly filled, then to visit the front and confer with the Ambulance Officer of the Division, ascertain that the depots are properly located and that the Ambulance Sergeants have been notified of their positions, then to report to the General Commanding and receive any instructions he may have; afterwards to return to the hospital and assist in making the wounded comfortable. 11. On the march the Surgeon-in-Chief of a Division remains with the General Commanding.

"*Duties of a Surgeon-in-Chief of a Brigade:* 1. The Surgeon-in-Chief of a Brigade has under his charge all the medical supplies allowed to his command. He draws once a month from the Medical Purveyor of the Army all needed to bring what he has on hand up to the requirements of the supply table, and in case of emergency can, during the month, make special requisitions for necessary articles. He issues to Medical Officers in charge of regiments only what they want for immediate use. By this excellent arrangement the Army has been relieved from the encumbrance of the large supplies formerly allowed to regiments and the transportation of the Medical Department is greatly reduced. Under two orders from Surgeon Letterman, Medical Director of the Army of the Potomac, Brigade Surgeons were forbidden, for more than a year, to take receipts from regimental Surgeons for supplies issued to them, and the Brigade Surgeon was ordered to expend them on his annual returns. This proving unsatisfactory to the Treasury Department, a circular from the Surgeon General directed a return to the requirements of Army Regulations in the transfer of all property. As medicines and other expendable articles are issued continuously, and in very small quantities, it is unavoidable for the Surgeon-in-Chief of a Brigade to be forced to expend, on his returns, much property really issued to regimental Surgeons. The transportation granted to each Brigade for its entire medical supplies, including the desks and medicine chests of regimental Surgeons, consists of one Army and one Autenrieth or Perot medicine wagon. In addition, however, to the articles carried in the wagons, the boxes of the ambulances are filled with the material necessary to establish a temporary field hospital in case the supply train during a movement is inaccessible. This arrangement is one of the greatest advances made during the past two years in providing for the wounded—as the conveyances bringing them in have all that is absolutely required to feed them, and the hospital tent and fly generally carried in the ambulance gives sufficient shelter. In the construction of new ambulances it would be desirable to increase the width and depth of the box so that larger camp kettles could be carried, the present only admitting the smallest sized kettle. The Surgeon-in-Chief of a Brigade furnishes the material carried in the ambulance boxes, and assures himself by weekly inspections of them that each box contains all required by the supply table and other orders. He also draws from the Medical Purveyor and is responsible for the stretchers carried on the ambulances. 2. The Surgeon-in-Chief of a Brigade is the Medical adviser of a Brigade Commander in all professional questions affecting the command. Applications for leave of absence, discharge, and invalid rolls, grounded on the certificates of regimental Surgeons, are submitted to him for his opinion of their propriety, to be based on an examination of the applicant. It is the duty of the Surgeon-in-Chief of a Brigade also to keep careful watch over the health of the Brigade, pointing out and endeavoring to correct all infractions of hygienic laws. He receives every Saturday, from each Medical Officer in charge of the regiments constituting the Brigade, a weekly Report of Sick and Wounded of his regiment and of the anti-scorbutics issued to it. Whenever a regimental Medical Officer leaves or returns to his command he should furnish the Surgeon-in-Chief of the Brigade with a copy of the order under which he acts. The Surgeon-in-Chief consolidates the regimental weekly reports of sick and wounded and of anti-scorbutics, and forwards them to the Surgeon-in-Chief of his Division. He sends, at the same time, a report of the liquors drawn and issued by him during the week. He makes also, to the Surgeon-in-Chief of the Division, a monthly return of the Medi-

cal Officers of the Brigade. After a battle he sends to the Surgeon-in-Chief of the Division a report of the aggregate strength for duty and names of Medical Officers present for duty, and the killed, wounded, and missing in action, according to the reports received from regimental Surgeons. The losses in skirmishing in the intervals between the battles have been reported weekly.

"*Duties of the Surgeon-in-Charge of a Division Hospital:* The duties of a Surgeon-in-Charge of a Division Hospital are somewhat varied, depending upon the season of the year and the state of military operations, whether the Army is in winter-quarters or engaged in an active campaign. In one case more permanent arrangements are made with a view of remaining undisturbed for several months; in the other all the appliances of a Division Hospital are arranged and managed to meet certain conditions, definite transportation, general mobility, and despatch in its construction and removal. Procuring all the necessary supplies for the sick and wounded, superintending the care and treatment which they should receive, organizing the hospital attendants, keeping the necessary and suitable records, causing reports to be made, and receiving orders from his superior officers and complying with them, are briefly in the aggregate the duties of the Surgeon-in-Charge of a Division Hospital. On the march the sick and wounded on hand are placed in ambulances, and a Medical Officer connected with the hospital is assigned the duty of keeping with the ambulance train and rendering such assistance on the journey as the wants of the sick, etc., may demand. In the evening, or at the close of the day's march, the Surgeon-in-Charge will make the necessary arrangements for sheltering and furnishing the sick, etc., present, with food and medical attendance. This is often accomplished in this manner: The Medical Director of the Corps indicates to the Ambulance Officer the place he desires the ambulances to park. The Surgeon-in-Charge then proceeds to pitch a sufficient number of tents, directs the cooks to provide beef tea, hot coffee, etc., orders sinks to be dug, sees that the sick and wounded are unloaded and taken care of, thus affording them attentions and comfort consistent with the nature of circumstances. On the following morning, after food has been served to all, a 'Sick Call' is held, and all that require medicine receive it. Soon after, a morning report is made, signed by the Surgeon-in-Charge, and sent to the Surgeon-in-Chief of the Division. Thereafter, if it is intended to resume the march, the sick and wounded are reloaded, the tents are struck, and everything packed. Thus the routine continues from day to day as long as the march may last. In the event of an engagement, the Surgeon-in-Chief of the Division indicates to the Surgeon in charge of the hospital the place selected for the location of the Division Hospital. The latter then directs the pioneers or fatigue party to police the ground and pitch the tents, establishes the kitchen, appoints a chief cook and a cook for special diet, organizes the nurses and other attendants, unloads the ambulances of the sick, provides operating tables and all necessary appliances for surgical operations, such as chloroform, stimulants, dressings, etc., orders sinks dug, sees that a sufficient supply of water is near, either by opening springs or by digging wells, etc. Thus accommodations are made for the sick on hand as well as for the wounded that may be brought in from the battle-field. The Surgeon-in-Charge selects a Medical Officer to superintend unloading and disposing of the wounded as they come in. Such as require operations are taken to the tables and receive the attention of the Surgeons. Very often comfortable and convenient beds are made by filling sacks with hay or straw, raising them from the ground on crutches or cross-pieces. The Recorder's attention is then called to the wounded, and he takes down their names, rank, regiment, and character of injury, and, in order to prevent confusion, often finds it necessary to attach a small piece of bandage to the button-hole of the wounded man that he may be assured afterwards that his name, etc., has been registered. It is the duty of the Surgeon-in-Charge to see that the records are at the amputating tables and properly kept, specimens preserved and labelled, etc. He selects either a Medical Officer or a Hospital Steward to have immediate supervision of the kitchen, diet, and feeding of the men. He sees also that the wounds of all the wounded men are examined and dressed, and in order to secure this a sufficient number of Medical Officers are assigned to wards as dressers, and a Medical Officer, Surgeon, or Assistant Surgeon appointed each day to act as officer of the day. He is required to be on duty at night, also to attend to any emergency that may arise—sudden hæmorrhage, prostration, etc. The dead likewise require the duties of the Surgeon-in-Charge. He selects a suitable location for a cemetery and here inters the dead, giving them a Christian burial by the presence of a Chaplain to officiate and attend to the funeral obsequies. The graves are marked by a head-board, written or inscribed on it the name, rank, company, and regiment of the deceased. His effects are preserved and at a

convenient time disposed of according to the requirements of the Army Regulations. His duties consist, likewise, in making out provision returns and drawing from the Commissary of Subsistence a sufficient number of rations for the sick and wounded, as well as for the hospital attendants present. He should see to it that an abundant supply of chloroform, stimulants, beef-stock, blankets, bed-sacks, bandages, dressings, shirts, drawers, and socks is on hand to meet almost any emergency that may occur. When the sick and wounded are ordered to be sent to the 'Depot Hospital' a list of them will be made out complete, which, when approved by the Medical Director of the Corps, will be sent with the Medical Officer who accompanies them. A proper entry of the disposition of these will be made in the register. The supervision of the Hospital Fund made from the savings devolves upon the Surgeon-in-Charge. He will keep a correct account of it, and authorize the purchase from it of such delicacies as are needed for the comfort of the more serious cases in the hospital. The Surgeon in charge of the hospital is immediately subject to the orders of the Surgeon-in-Chief of the Division, and such other orders as may come through him from higher authority—Medical Director of Corps and Army. His reports should be made through the same channel, also the requisitions for Medical Supplies, requests for details, etc., and in fact all official communications whatever, except property returns, which go directly to the Department of the Surgeon-General. The following is a list of reports, requisitions, etc., made by the Surgeon in charge of the hospital: A Weekly Report, Monthly Report, Report of Sick and Wounded, Certificates of Death, Requisitions for Medical and Hospital Stores, Morning Reports, etc. The following is a list of the books and registers kept on hand: Morning Report Book, Register, Prescription Book, Case Book, Letter and Order Book.

"*Duties of the Medical Recorder of a Division Hospital:* 1. During a battle the names of all wounded admitted to the hospital are carefully entered in the prescribed forms: Lists of Wounded, giving Rank, Company, Regiment, and Corps; also the nature of the missile or weapon causing the injury, when wounded, its nature (slight or severe) and the treatment pursued in each case. On this form are also entered all amputations and operations and deaths. After the engagement is over a Classified Return of Wounds and Injuries is prepared from this list. 2. At the operating table an assistant prepares all specimens of interest for preservation in a specimen jar. Here, likewise, the name and designation of the patient is noted down, with a full detail of the injury and the operation performed, with the name and rank of the operator. When the specimen is ready to be deposited in the jar it is labelled and the number on the label written opposite the patient's name. As soon as possible afterwards, a complete list is made of all the operations during the engagement, giving, as it were, a history of each case, the number opposite the patient's name corresponding with the number of the specimen in the jar. After a battle a report of aggregate strength of men and names of Medical Officers present for duty is also made out.

"*Duties of the Attending or Prescribing Surgeon of a Division Hospital:* 1. To visit his ward regularly twice each day, or as often as the condition of his patients may require. 2. To examine and make proper diagnosis of patients as they may be reported to him, either for wounds or disease; to make and keep a correct register of all patients, with their treatment, and daily to report them to the Surgeon in charge of the hospital. 3. To prescribe suitable remedies and to see that they are regularly administered by the attendants. 4. To inspect the diet of the men and see that proper food is given them. 5. To attend strictly to the sanitary condition of his ward and surroundings, and compel those whose duty it may be to remove everything offensive or detrimental to health. 6. To assist in all surgical operations, or operate, as he may be required by the Surgeon assigned to that duty. 7. To see that the men under his care are as comfortable as circumstances will admit.

"*Duties of the Operating Surgeon:* 1. The Operating Surgeon shall select steady and reliable attendants, give them clear and explicit instructions relative to their respective duties, and assign to each his proper place. 2. He shall see that all the necessary appliances be at hand required in performing operative surgery, that the instruments are in good order and in their proper places, and that a good and sufficient supply of lint, bandages, ligatures, sponges, plaster, etc., be conveniently placed and ready for use. 3. He should take charge of all patients that in the opinion of the Prescribing Surgeon require surgical attention, make a minute and thorough examination of each case and determine whether surgical aid is necessary; judge of the best manner of benefiting the patient, taking into consideration the relation of important organs, vessels, and nerves in

proximity to the wound, what bearing they may have in the preservation or loss of the patient's life, and to use every preservative means within the reach of surgical science to save the life of the patient with as little impairment of all his functions as possible. 4. An operation being determined upon, he should have the patient properly placed upon the table and should judge of the practicability of administering anæsthetics, and if their use is found necessary should superintend the administration. 5. The patient being etherized, the Surgeon proceeds with the operation that the case requires in the most expeditious and scientific manner compatible with the nature of the injury, endeavoring to preserve the usefulness of the parts operated upon to the greatest extent—in operations on the extremities preserving as great a length of bone as possible and securing sufficient integument to give a liberal covering to the stump.

"*Duties of the Regimental Surgeon:* The first duty of the day is that of the Morning 'Sick Call,' when the sick and disabled, as well as those who are neither sick nor disabled, present themselves for treatment. The Surgeon is called upon to exercise his judgment in determining the character and gravity of their ailments. If he had none to deal with but those who were really sick, his task would be plain, simple, and easy; but, unfortunately, many of the cases are feigned, and he is required to discover and overcome the means brought into requisition by a skulker's ingenuity to carry out his deception. Presuming that the Surgeon is fortified by skill and experience sufficient to detect these, and has a just sense of responsibility to the United States Government (for he really regulates the strength of the command), his examinations will be made without partiality and regardless of position or prejudice, and in his report he will assign to duty those who are fit for duty, the sick to quarters for treatment, or send them to hospital, and recommend the permanently disabled for discharge or the Veteran Reserve Corps. It may be added that in cases having slight symptoms of diseased action, insufficient to indicate position and unmistakable disease, humanity would dictate, and authority sanctions, that they be placed off duty, and that they may have the benefit of the doubt and time for development of disease. Having concluded his work thus far, the Surgeon will see that a copy of his report is forwarded to the Adjutant, who deducts all excused from duty from the mean strength present in the regiment; and the available strength of the command is obtained, which forms the basis for all details and assignments that may be made in the regiment. Should the regiment be filled up by conscripts, substitutes, or enlisted men, the Surgeon is required to examine each one carefully and report on their fitness for service, rejecting all those who, by reason of infirmity, are unfit, and recommending for reception such as he thinks will be able to discharge the duties of a soldier. That the duties imposed upon the Surgeon are important is obvious to any one, and should be particularly so to an officer who has recorded his obligation to subserve the interest of the United States. If the Surgeon indulges the men and reports them off duty when they are not sick, he imposes additional labor on the faithful men who bear the heat and burden of the day, and virtually offers a reward to the faithless; or in examining recruits admits any who are physically disqualified, he acts in bad faith to all and in the end unwarrantably weakens the command, defrauds the Government, and may be the cause of rendering an important engagement abortive. If he conducts his examinations carelessly, the men will soon avail themselves of the chance to escape duty, and in great numbers report themselves sick; the Surgeon loses his influence for good, and he sinks into disrepute and merited disgrace, which does not terminate with his service in the Army, but will follow him throughout all time. After 'Sick Call' the Surgeon should visit the sick in quarters, prescribe for them, and see that suitable food is provided and their quarters made as comfortable as possible, inspect the camp daily, see that it is well drained by proper ditching through which all superfluous or surface water may be carried off, that all filth or anything likely to produce disease is removed or corrected, that the quarters of the men are swept and aired and their bedding exposed to the sun whenever practicable, that the sinks are covered with dirt or ashes (the latter preferable), that the food of the men is of good quality and sufficient quantity (reporting any error in either), and that the cooking is judiciously done. These duties are essential and should receive daily attention, as the neglect thereof will decidedly increase the sickness of the regiment and consequently impair its efficiency. Should a soldier die in camp or regimental hospital, the Surgeon should notify his Commanding Officer and forward to him an inventory of his effects, with the disease from which he died and the date of death, select a place for burial and see that he is decently buried and his grave carefully marked. The duties thus far pointed out are obligatory, and no excuse can be made for their non-perform-

ance in camp. There are many other acts of kindness, more correctly denominated 'favors,' that can be extended by a Surgeon without detriment to himself, that will have a good effect upon the soldier in leading him to believe that his life and comfort command the Surgeon's consideration; these being done willingly will have the effect of improving the morale of the command and usefulness of the Surgeon. When a march is likely to be made the Surgeon is directed to send his sick to General or Division Hospital. Again he is called upon to make a careful and rigid examination to avoid imposition; for the terrifying effect of a prospective battle will cause men to limp who never limped before, and many hitherto good soldiers will make an effort to escape it. The Surgeon completes his list and forwards a copy by name, rank, and company, regiment, and disease, with descriptive lists of each man; when he loads his men, providing sufficient food for the time required to reach the hospital. Having provided the requisite quantity of medicines, etc., to fill the 'hospital knapsack' or 'field companion,' he gives them to his hospital attendants, and when the regiment moves the Surgeon, Hospital Steward, and attendants take their position in the rear. If any of the command take sick or are wounded on the march, the Surgeon is notified and is prepared to prescribe medicines or suitable dressings, and furnishes a pass for ambulance transportation (a duplicate of which he retains), or directs them to walk leisurely in the road, being governed by the severity of the diseases or wounds, and being careful that no deception is practised by men that are not sick, recording each case in his 'Field Register,' with character of disease or wound. Having thus carefully discharged his duties during the day, and though the march has been a long and laborious one, he should, after arriving in camp, visit and prescribe for the sick, and endeavor to make them as comfortable for the night as the means at hand will permit, before his day's work is done. Again, in the morning, before the regiment moves, he should see them and prescribe medicines for the day, select such cases as require wagon transportation, see that they are loaded, and those able to march started before he leaves the camp. From day to day these duties should be performed. Although trying on the strength of the Surgeon he should not fail to do them, as, sooner or later, a day of rest will come and he will be able to recuperate. During an engagement the Surgeon, if not detailed on the operating staff at the hospital, should report with his assistants and attendants to a point selected in the rear of his command, either by brigade or regiment, and notify the sergeant in charge of the stretcher bearers thereof, that the wounded may be carried to said point, to whom he should give such medicines and apply such dressings as their wounds may require, to afford comparatively comfortable transportation to the hospital of their Division, where each case receives minute examination and further attention. Should the Surgeon be placed on the operating staff, his duty, in connection with other members, is to examine carefully every wounded man and determine the extent of his wound, the parts involved, and the necessity for and kind of operation his case may demand. Should he be selected to perform the operation he should endeavor to do it as scientifically and with as much despatch as the nature of the case and safety of the patient will admit, and in all cases apply appropriate dressings in such a manner that they will not become detached in transportation to General Hospital. He may be thus employed for an indefinite length of time; he should therefore feel it incumbent on him to labor as long as there are any cases requiring attention, until all have had the advantage of primary operations and are relieved from the excessive pain of undressed wounds and increased mortality attending secondary operations. The duties of the Surgeon in every position may be summed up in one sentence: He does not rest until everything is done that can contribute to the comfort of the wounded. After a battle the Surgeon will report to his regiment, unless otherwise ordered, and resume the charge thereof, and will perform such duties as are mentioned in describing those in camp, etc., previously procuring the names of the men killed in the action, and of the wounded, the nature of their wounds and character of the missile inflicting them, together with all statistics required in reports he may have to make. The reports required of a Surgeon of a regiment are the 'Morning Report' to the Adjutant, the 'Weekly' to the Surgeon-in-Chief of the Brigade, and the 'Monthly.' It is altogether necessary that a medical officer should so conduct his department that he may secure the confidence of the officer in command of the regiment to which he is attached, that said officer may receive his reports and rely on their correctness. If both military and medical officers are sincerely interested in the health of the regiment and act in concert, much can be done to promote order and discipline. The necessity for this can be discovered when the opposite is experienced. The Surgeon cannot have an order issued or carried into effect without

great difficulty, and if the variance should continue the intercourse will be so unpleasant that the command eventually suffers in consequence. The officers are mutually responsible and should be mutually respectful.

"*Duties of the Assistant Regimental Surgeon:* The duties of an Assistant Surgeon when in charge of a regiment or hospital are identical with those of a Surgeon in the same position. If he be acting under a Surgeon in charge he will perform such share of the Surgeon's duties in the case of the sick as the Surgeon may assign to him. The sick in the ambulances on the march are usually put in charge of an Assistant Surgeon, one or more, whose duty it is to accompany the ambulances and see that such medicines are administered as the patients may require; usually he both prescribes and dispenses. He decides also what patients must be carried, and when they are well enough to walk or to rejoin their companies. Beef stock, tea, and sugar are carried in each ambulance for the use of the sick, subject to the order of the Assistant Surgeon in charge, and to be prepared by the ambulance men belonging to each ambulance. When an action is about to take place the Surgeons with the regiments are usually ordered to the Division Hospital, while the Assistant Surgeons are left to establish regimental field hospitals or depots, where the wounded come or are brought by the stretcher bearers to be dressed. Sometimes a Surgeon is left in charge of the Assistant Surgeons of a Division with orders to select the places for the field hospitals. A depot of this kind should be in some comparatively safe place, but not too far from the regiment, and where the ambulances can have a good chance to come without being in great danger from the enemy's fire; it should also be convenient to good water, which will be needed for dressing the wounded. If the place is too much exposed the stretcher men will not be likely to bring the wounded, nor will wounded men wish to be left where they may get more wounds while being dressed or waiting their turn to be attended to; but will prefer to go farther to the rear. If the ambulances cannot come to the depots where the men are brought to be dressed, a sudden change in the lines may cause some men to be left on the field who were waiting to be attended to, and who might have been carried off in a very few moments if necessary, even though they were not dressed, were the ambulances there. Still, although perfectly safe places can seldom be found near where the fighting is going on, especially where the ground is comparatively even, the Assistant Surgeon should not allow his fears to induce him to remain too far away from his men, and they should be kept advised of his whereabouts; hence, when a regimental field hospital has been established it should not be moved unless it is absolutely necessary to do so. . Assistant Surgeons on the battle-field should be furnished with the ordinary Surgeons' dressing case of instruments —operations requiring other instruments than these are usually of too severe a character to be attempted on the field. He should be accompanied by one or two nurses with plenty of lint, bandages, isinglass plaster, water, sponges, and a few of the most frequently required medicines. After dressing the men the Surgeon should see that they are properly placed in the ambulances, and give the direction for their care until they reach the Division Hospital—duties often of great importance to the patient. When it can be done conveniently it is better that the Assistant Surgeons of several regiments or of a Brigade be together on the field, as they will often be enabled to assist and advise each other. An Assistant Surgeon in the field has very little opportunity for observing severe surgical cases; after the first dressing he very rarely sees or hears anything of their further treatment or termination. So far as practicable the Assistant Surgeon in the field should keep a memorandum of the names of the men he dresses, their companies and regiments, also the character and severity of their wounds; this will be of much service in making the required reports and in answering the inquiries of anxious friends. Of the relative position of an Assistant Surgeon very little is to be said. He seems to be subject to the orders of the commander of his regiment, brigade, etc., whether he be colonel or corporal, and to those of the Surgeon of his regiment, brigade, division, etc., and has command only over those of inferior rank in his own department. So far, however, observation leads to the belief that regimental commanders seldom interfere with the duties of their Assistant Surgeons.

"*Duties of the Commissary of Subsistence of a Division Hospital:* The Division Hospital Commissary is under the immediate direction of the Surgeon in charge of the hospital; he makes reports to him and receives his orders. His duties while in camp are to draw at stated intervals from the commissary officer, authorized to issue to the hospital, such stores as are required for the use of the sick and wounded, stewards, and authorized attendants, on provision returns approved

by the Surgeon in-Charge. He is required by existing orders to keep on hand at least one thousand rations of bread, sugar, coffee, tea, pork, and from six to ten head of beef-cattle. He makes a daily inspection of the stores on hand in order to keep up the necessary amount of supplies, so as to be ready at all times for a rapid movement or an engagement. It is also his duty to make out the provision returns, having them agree with the morning report of sick and wounded; the names of all the hospital attendants to be written on the back of each return. He superintends the purchase of such articles as are not furnished by the Government, and which the Surgeon-in-Charge considers necessary for the use of the sick and wounded. He also keeps an account of the savings of the hospital, and makes a monthly report of the state of the hospital fund to the Surgeon-in-Charge. He has, in conjunction with a medical officer, charge of the cooking and preparation of the food, seeing that there is no unnecessary waste, and that the place in which the stores are kept and food prepared is properly policed daily. When orders to move are received he attends to the packing of the supplies in the wagons assigned for that purpose. He also sees that there is a sufficient number of cooking utensils on hand, and that they are kept clean and in good condition. On the march he is required to keep his wagons with the hospital department, or wherever they may be ordered, also to have the beef-cattle up with the wagons, so that if necessary they can be slaughtered and prepared for food in the evening, or whenever a halt is ordered. He selects a proper place for cooking purposes, unloads such stores as are required for the occasion, and, if within reach of the supply train, gets his stock replenished. On the approach of an engagement it is his duty to have hot coffee, tea, beef-soup, and other necessary articles of diet ready for the wounded as soon as they may be brought in from the field. When the wounded are being sent to the depot hospital he furnishes each man with sufficient rations to last him until he reaches his place of destination. When men are returned to duty from the hospital he also furnishes them with rations.

"*Duties of the Chief Ambulance Officer of a Corps:* In addition to the regular monthly returns of Quartermaster's property the Chief Ambulance Officer of the Corps receives and makes the following reports: 1, Daily Wagon and Forage Report; 2, Weekly Ambulance Report; 3, Monthly Report of Transportation; 4, Monthly Report of Officers in Quartermaster's Department of the Ambulance Train and the time to which they have made their property returns; 5, Monthly Report of all Quartermaster's property received and issued during the month; 6, Monthly Report of Officers serving in the Ambulance Train. When not on the march the Chief Ambulance Officer of the Corps inspects the ambulance train every Sunday morning with the object of correcting all abuses and of promoting the efficiency of the train. Before a move he should give timely notice to the Division Ambulance Officers, so that they may have everything packed up and ready to start at the appointed hour. It is his duty to regulate the order of march of his train, select suitable camping grounds, and see that his train is at all times ready for active service. Before an engagement he informs himself as well as possible about the country, roads, etc., sees that his train is well up and together, so that as soon as the lines of battle are established he can park his whole train in some central position from which to send picket ambulances as near the lines of each Division as possible. An officer is always placed in charge of the main park of ambulances, one in charge of the picket ambulances of each Division, and the remainder of the officers are instructed to take charge of the stretchers, men, and sergeants. It is also necessary to leave an officer in charge of the hospital train of the corps. The Chief Ambulance Officer must personally superintend the working of his train so as to see that every one does his duty, that the drivers do not become stampeded, and that the wounded are transferred to the hospital as quickly and easily as possible. It is also his duty to see that the stretcher men do not carry the wounded farther than is necessary. When in camp, and it is necessary to send off sick or wounded, the chief Ambulance Officer orders the proper number of ambulances and details an officer to take charge of the train; one ambulance officer from each Division superintends the loading of the ambulances at his Division Hospital. When in camp, the stretcher men are used in the hospital when needed. It is also necessary that the Chief Ambulance Officer should see that the ambulances are not improperly used. It being desirable to receive orders as early as possible, the Chief Ambulance Officer finds it best to have his quarters at Corps Headquarters.

"*Duties of the Chief Ambulance Officer of a Division:* He should be the receipting officer for all Quartermaster's property belonging to his Division, and be responsible for all deficiencies. He should make all necessary returns required by the Quartermaster's Department, Commissary

Department, and Ordnance Department, viz: Monthly returns of property to the Quartermaster's Department, Quarterly return of Ordnance, usual Ration return to Commissary Department, also the daily Forage Report, the Weekly report of Ambulance Department, Monthly report to Quartermaster's Department, and Monthly report of Officers. When on the march he should attend to the running of his train, see that forage is drawn from the nearest post, and a sufficient quantity kept constantly on hand; properly park his train at night according to orders from the Chief Ambulance Officer of the Corps; necessary sentries posted so that horses may not stray away or be stolen, and be ready to move at short notice. Before an engagement it is his duty to see that the Brigade Officers are with their Brigades, and that they have the sergeants and stretcher bearers well up with their regiments, have his train so parked that it will be easy of access, and so near that the stretcher men will not have any farther than actually necessary to carry the wounded, and at the same time protect his horses from unnecessary exposure; and after an engagement to assure himself that all the wounded of the Division have been removed from the field; also to assist the Surgeons when a train of sick and wounded is to be sent to Base or General Hospital.

"*Duties of the Chief Ambulance Officer of a Brigade:* 1. While in camp one Brigade Officer of each Division train is constantly with the troops, and in case of any movement reports the fact at once to the Chief Ambulance Officer of his Division. He should see that the drivers and stretcher men are at the established posts, and that all orders from Surgeons for ambulances or stretchers for the transportation of sick or wounded men are promptly attended to. 2. When not on duty with the troops he will see that the ambulances are properly parked, and that the drivers attend faithfully to the feeding and grooming of their horses, the cleaning of the harness and ambulances, and to the policing of the stables and grounds of the park; also that the kegs are kept constantly filled with fresh water. Stretcher men will assist in the policing when not on duty at the Division Hospital. 3. A suitable non-commissioned officer will be selected to have the direct supervision of the ambulances of the Brigade, and another of the stretcher men. The rest of the non commissioned officers will have charge of the stretcher men of their respective regiments under the one in charge of the stretcher men of the Brigade. 4. On the march (unless otherwise directed) Brigade Officers remain with the headquarters of their Brigades, and in case of an engagement select a spot as near the line as possible, with a reasonable degree of safety to the horses, and as central to the lines of the Brigade as possible. 5. The Brigade Officer will cause a small number of ambulances to be brought to the spot selected, and others to be sent to fill their places; and as fast as they are filled to send to the place selected for the hospital. The stretcher men will be informed of the position of the ambulances, and will bring to them as fast as possible any man that may be wounded and unable to walk, until all the wounded men are carried from the field. 6. The Brigade Officer should inform himself of the shortest and best roads to the Division Hospital, and see that the drivers take them, driving carefully, and avoiding the bad places as much as possible on an uneven road. A good non-commissioned officer should remain constantly with the advanced ambulances to see that the wounded men are loaded carefully and speedily and the drivers do not get demoralized. 7. No written reports are made by Brigade Officers. They report verbally to the Division Officer any breach of discipline or neglect of duty that may require his attention. 8. He receives only such orders as come through the Chief Ambulance Officer of the Corps or his Division, or some medical officer."

It is only necessary to point to the manifold functions required of the medical officers in the foregoing reports to see that their duties were arduous and responsible, calling, aside from professional ability, for the exercise of firmness combined with tact and moderation to do justice to the sick and wounded entrusted to their immediate care, and at the same time to avoid complications with clashing interests.

MATERIA CHIRURGICA.

At the beginning of the war each regimental Surgeon was furnished with a suitable equipment for his regiment for field service, consisting of medicines, stores, instruments, and dressings, in quantities regulated by the Standard Supply Table.[1] In action he was

[1] See *Standard Supply Table for Field Service*, in *Revised Regulations for the Army of the United States*, 1861, p. 304.

accompanied by a hospital orderly, who carried a knapsack containing a limited supply of anæsthetics, styptics, stimulants, and anodynes, and material for primary dressings. This hospital knapsack had been recommended for adoption by an army board in 1859; it was made of light wood, 18 inches in height, 15 inches wide, and 7½ inches deep, but subsequently

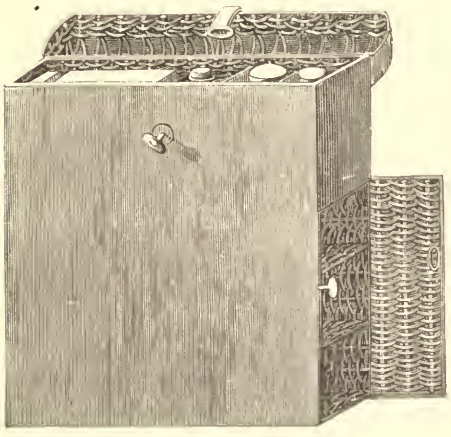

FIG. 425.—Hospital knapsack of wicker-work, covered with enamelled cloth.

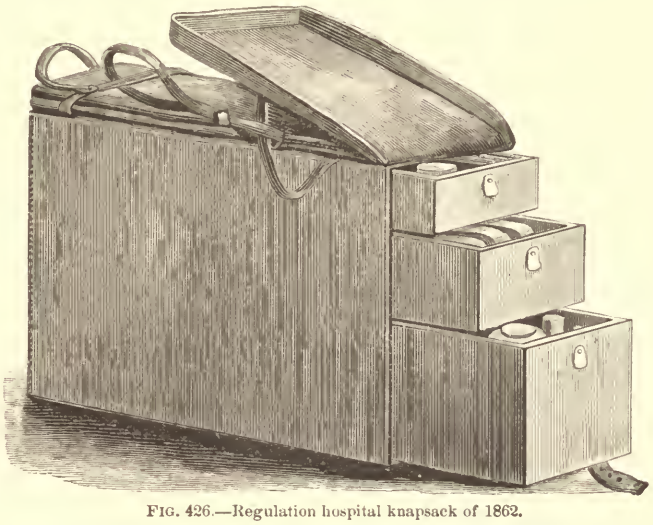

FIG. 426.—Regulation hospital knapsack of 1862.

wicker-work, covered with canvas or enamelled cloth, was substituted for the wood; its weight when filled was 18 pounds. This knapsack (FIG. 425) was in general use in the first year of the war and served an excellent purpose. In 1862 it was changed for what was known as the new regulation knapsack, in which the arrangement and character of the supplies were modified. The new pattern was 16 inches high, 12½ inches wide, and 6 inches deep; the contents were packed in drawers, which were more accessible than in the old style and less liable to become disarranged or broken.[1] The weight when packed was nearly 20 pounds (FIG. 426). Notwithstanding its convenience and general adaptability it was too heavy and cumbrous to be carried by the Surgeon himself, and, when entrusted to other hands, was liable, in the vicissitudes of battle, to be lost. In the early part of 1863 Medical Inspector R. H. Coolidge, U. S. A., arranged a field case or companion[2] (FIG. 427) to take the place of the knapsack. It was something after the plan of the one used in the British service, and was intended to be carried by the Surgeon himself, if necessary. The "companion" is a leather case 13 inches long, 6 inches wide, and 7½ inches deep; it is supported by a strap passing over the shoulder, and is provided with a waist strap to steady it when carried.

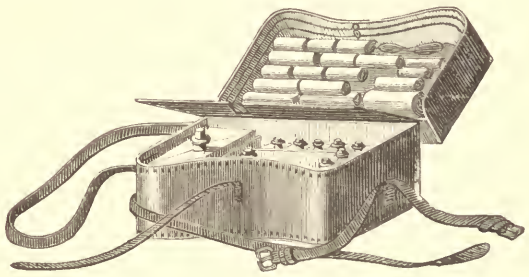

FIG. 427.—Surgeon's Field Companion.

The hospital medicine chest, mess-chest, and bulky hospital supplies were transported in wagons of the supply train and were often inaccessible when required. To obviate this

[1] The contents of the knapsack were: One piece of white wax, 8 oz. simple cerate, 12 oz. chloroform, 5 yds. adhesive plaster, 2 yds. isinglass plaster, 1 oz. persulphate of iron, 100 compound cathartic pills, 150 blue mass pills, 150 opium pills, 100 opium and camphor pills, 150 quinine pills, 8 oz. aromatic spirit of ammonia, 16 oz. brandy, 4 oz. laudanum, 10 bandages, 10 binder's boards, 4 oz. charpie, 2 medicine glasses, 1 (spirit) lamp, 12 oz. lint, 1 box matches, 1 paper of pins, 1 spool of surgeons' silk, 4 pieces of sponge, 4 (Dunton's) field tourniquets, 2 spiral tourniquets, 1 piece of tape, 1 spool of lead wire, 1 spool of silver wire, and 1 spatula.

[2] The contents of the Surgeon's Companion were: 6½ oz. chloroform, 2 oz. fluid extract of ipecacuanha, 2 oz. fluid extract of ginger, 2 oz. solution of persulphate of iron, 24 oz. of whiskey, 2 oz. tincture of opium, 144 compound cathartic pills, 144 colocynth and ipecacuanha pills, 144 sulphate of quinine pills, 144 opium pills, 1 yard isinglass plaster, a medicine cup, scissors, teaspoon, pins, thread, 4 oz. lint, a towel, 2 doz. bandages, muslin, and corks.

inconvenience panniers were provided containing the most necessary medicines, dressings, and appliances; they were designed to be carried on the backs of pack-animals, but were found to be inconveniently heavy to be transported in this manner, and were more generally carried in one of the ambulance wagons and filled from the medicine chest as required. Figs. 428, 429 represent the pannier arranged for army use by Dr. Squibb, of Brooklyn, N. Y.; it consists of a wooden box strongly bound with iron, 21⅛ inches in length, 11⅝ inches in breadth, and 11⅜ inches in depth; it weighs, when filled, 88 pounds. The medicines are well packed in japanned tin bottles and boxes, and room is left for an adequate supply of dressing material. The pannier had two compartments.[1]

Fig. 428.—Medicine pannier.

In the early part of the war medical supplies and instruments had been carried in heavy army wagons. In March, 1862, a medicine wagon was constructed by E. Hayes & Co., of Wheeling, Virginia, in accordance with plans and instructions of Surgeon Jonathan Letterman, U. S. A. Details of the internal arrangement of this wagon could not be obtained. A Board, consisting of Brigade Surgeon William Hayes and Assistant Surgeons Hammond and Dunster, U. S. A., on April 17, 1862, examined the wagon and reported as follows: "The merits of this dispensary wagon are so apparent, when compared with the old method of packing medicines and instruments in unwieldy boxes and transporting them in the heavy army wagons, that the Board unanimously approves of the same, and recommend that it at once be sent into the field where it can be practically tested. The adoption of a vehicle of this or some similar construction for the transporting of medicines, etc., in the field would be an actual saving in transportation over the present plan, as a three months' regimental supply can be carried with ease in a single wagon dispensary. The advantage accruing from the prevention of loss by wastage and breakage, the convenience of having the whole together and unencumbered by other baggage, and the readiness of access to medicines, instruments, and dressings in case of an emergency, are so palpable that it is only a matter of surprise that some such plan has not been previously adopted."

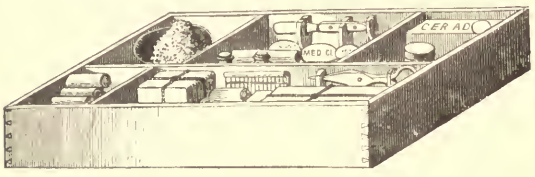

Fig. 429.—Upper tray of medicine pannier.

In November, 1862, Mr. J. Dunton proposed a medicine wagon, a drawing of which is shown in Fig. 430. It was examined by Medical Inspectors T. F. Perley and J. M. Cuyler and Surgeons J. Simpson and J. H. Brinton, who reported, on November 3, 1862, that it was questionable whether it would answer the purpose for which it was designed, as it was faulty in construction, and its capacity insufficient to accommodate the entire hos-

[1] The upper compartment contained 24 roller bandages, 1 yd. of isinglass plaster, 1 paper of pins, 2 yds. bleached muslin, and 1 pair of scissors. In the lower compartment were 6½ oz. purified chloroform, 2 oz. fluid extract of ipecacuanha, 2 oz. fluid extract of ginger, 2 oz. liquor of persulphate of iron, 12 doz. compound cathartic pills, 12 doz. quinine pills (3 grs. each), 12 doz. opium pills, 12 doz. pills of compound extract colocynth (3 grains) and ipecacuanha (½ grain), 24 oz. whiskey, 2 oz. tincture of opium, ¼ lb. patent lint, 1 medicine glass, 1 tinned iron teaspoon, 1 small piece fine sponge, ¼ oz. silk for ligatures, 1 towel, and 6 corks.

pital supplies for a regiment for three months." The wagon could be elongated at both ends, or closed, as was desired, and was arranged so as to be opened on the side.[1]

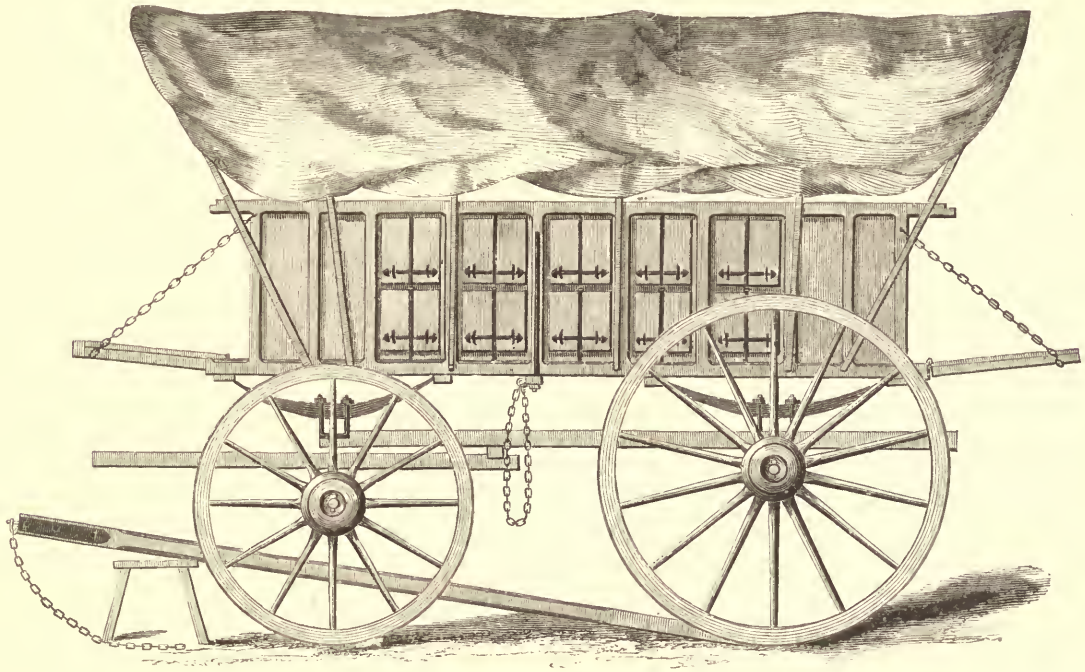

FIG. 430.—DUNTON'S regimental medicine wagon.

As the organization of the medical staff was perfected, the cumbrous regimental supplies were curtailed and the brigade supplies augmented. Each brigade was provided with a "medicine wagon," which was furnished not only with drugs but with ample provision of stores, dressings, furniture and appliances, an amputating table, and a limited amount of bedding. The contents of the medicine wagon were constantly replenished from the stores of the medical purveyors who accompanied each army. FIGURE 431 represents the medicine wagon of Perot.[2] While the internal fixtures and arrangements for transporting supplies in this wagon were excellent and convenient, the cost of furnishing it was very great, and on the recommendation of a Medical Board consisting of Surgeons C. H. Crane, R. O.

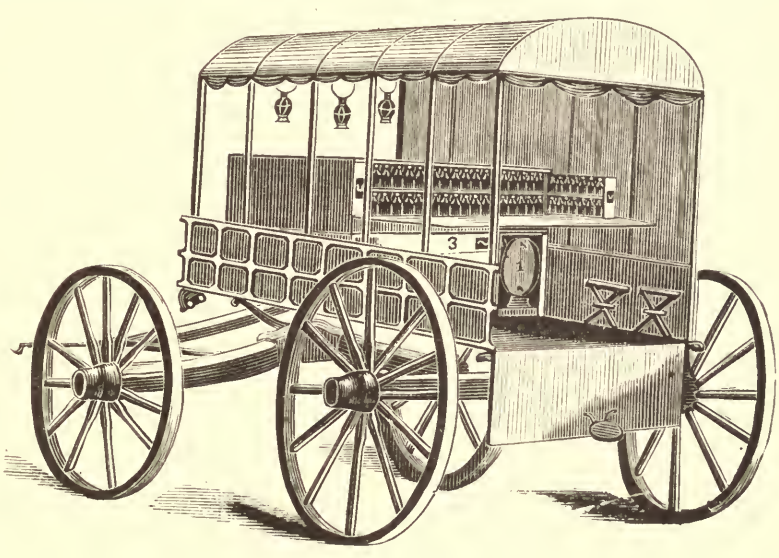

FIG. 431.—PEROT'S medicine wagon.

[1] This medicine wagon is erroneously designated by Professor T. LONGMORE (*A Treatise on the Transport of Sick and Wounded Troops*, London, 1869, page 386) as a United States Sick Transport Wagon with side and end openings.

[2] CONTENTS OF PEROT'S MEDICINE WAGON.—*Drawer* 1 contained an oval keg for 6 galls. of whiskey, with a cock on top and bottom, one to let in air, the other to draw from. This keg is on a skid and can be drawn out and filled at the bung. *Drawer* 2: Stronger ether for anæsthesia, 32 oz.; sweet spirit of nitre, 32 oz.; solution of ammonia, 32 oz.; turpentine, 1 qt.; castor oil, 4 qts.; brandy, 6 qts.; olive oil, 2 qts.; purified chloroform, 32 oz.; copaiba, 32 oz.; sulphate of quinia, 10 oz.; syrup of squill, 4 lbs. (part in *Drawer* 9). *Drawer* 3: 1 sponge-holder for throat, 12 probangs, 1 hinged tongue depres-

Abbott, and Charles Sutherland, U. S. A., in June, 1864, the Autenrieth pattern[1] (FIGS. 432, 433) was furnished to the army. An improved wagon, recommended by the Medical Department and constructed at the Government shops, was adopted during the last year of the war.

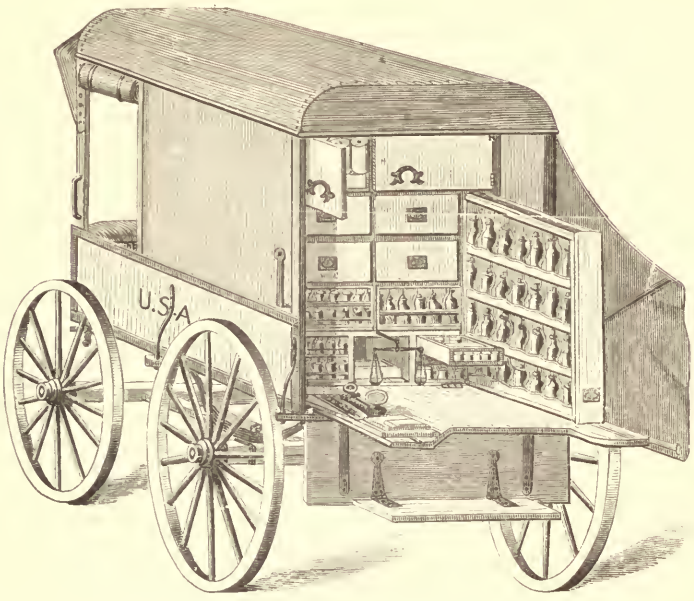

FIG. 432.—AUTENRIETH medicine wagon.

Surgical instruments were furnished by the Government, each medical officer making requisition for his equipment, receipting for it, and becoming responsible for its condition while in his possession; no transfers were allowed, and an annual return was required to be made to the Surgeon General. On leaving the service it was turned in to the nearest medical purveyor, who receipted for the same. The instruments intended for surgeons and assistant surgeons of the regular and volunteer staff were comprised in three cases—one for capital operations, containing amputating, trephining, and

sor, 4 single trusses, 2 bottles ink, 1 bottle mucilage, 1 U. S. Dispensatory, 1 portfolio (cap size), 2 quarto blank books, 1 order and letter book, 4 quires writing paper, 1 register of patients, 1 Gray's Anatomy, 1 Erichsen's Surgery, 1 Packard's Minor Surgery, 1 Longmore on Gunshot Wounds, 1 tooth-extracting case (army pattern), 1 8-oz. hard-rubber syringe, 1 self-injecting rubber syringe, 2 thumb lancets, 12 hair pencils, 2 scarificators. *Drawer* 4: Closet for 3-gall. can of alcohol, and a vacant drawer for any articles desired. *Drawer* 5: 1 set splints (6 forearm, 4 leg, 6 large coaptation, 4 small coaptation), 2 papers pill boxes (turned wood), 1 pair pliers, 1 gimlet, 1 tape measure, 8 pieces binder's board (4 x 17 inches), 8 pieces binder's board (2½ x 12 inches), razor strop in case, 1 file, 6 glass penis syringes, 1 corkscrew, 1 set Aiken's tool pad, 8 oz twine (½ coarse), 1 hone, 1 razor. *Drawer* 6: 2 quires wrapping paper (white and blue), 2 oz. ligature silk, 1 oz. linen thread (unbleached), 2 papers pins, 4 pieces cotton tape, case containing 25 needles, 1 spool cotton and thimble, 1 yard gray silk for shades, 8 field tourniquets, 2 screw tourniquets with pad, 12 cupping tins, 2 scissors (large and small), 1 pocket case, 1 box for sundries, 100 printed envelopes, 1 traveller's inkstand, 24 steel pens, 2 pen-holders, 6 lead-pencils No. 2, 1 stick sealing wax, 1 sheep-skin (dressed). *Drawer* 7, *Dispensing Case:* 1 Wedgewood mortar, 2 doz. vials (6 6-oz., 12 4-oz., 3 2-oz., 3 1-oz.), 1 pill tile (6 x 8 inches), 8 oz. fine sponge (small pieces), 1 tin funnel (pint), 5 yds. adhesive plaster, 4 lbs. patent lint, pestle for mortar, 4 yds. red flannel (all wool), 2 medicine measuring glasses, 2 yds. gutta-percha cloth, 5 yds. isinglass plaster, 8 doz. assorted corks, 1 glass graduated measure (4 oz.), 1 minim measure, 10 yds. bleached muslin, 2 cotton bats, 1 sheet cotton wadding, 1 set prescription scales and weights, 2 spatulas (3 and 6-inch), 2 glass urinals, 8 suspensory bandages, 2 lbs. scraped or picked lint, 2¼ yds. oiled silk, 2¼ yds. oiled muslin, 16 doz. roller bandages, assorted (2 doz. 1 inch by 1 yd., 4 doz. 2 ins. by 3 yds., 4 doz. 2½ ins. by 3 yds.. 2 doz. 3 ins. by 4 yds., 2 doz. 3½ ins. by 5 yds., 1 doz. 4 ins by 6 yds., 1 doz. 4 ins. by 8 yds.), 10 lbs. pressed tow, 1 doz. towels, aromatic sulphuric acid, tannic acid, spirit of nitrous ether, stronger ether (for anæsthesia), strong alcohol, alum, aromatic spirit of ammonia, purified chloroform, Dover's powder, sulphate of morphia, olive oil, castor oil, laudanum, paregoric, acetate of lead, bicarbonate of potassa, creasote, fluid extract of colchicum seed, fluid extract of aconite root, fluid extract of ipecac, fluid extract of seneka, tincture of chloride of iron, solution subsulphate of iron, pure glycerin, chlorate of potassa, iodide of potassium, bicarbonate of soda, whiskey, syrup of squill, blue mass, citrine ointment, powdered squill, Hoffman's anodyne, carbonate of ammonia, solution of ammonia, camphor, collodion, copaiba, sulphate of copper, alcoholic extract of belladonna, fluid extract cinchona (aromatic), fluid extract ginger, mercury with chalk, oil of turpentine, eroton oil, permanganate of potassa, Fowler's solution, chlorinated solution soda, solution chloride zinc, resin cerate, simple cerate, powdered gum arabic, nitrate of silver (crystals), fused nitrate silver, sulphate cinchona, citrate iron and quinia, powdered subsulphate iron, iodide of iron, powdered ipecac, powdered opium, pills of camphor (2 grains) and opium (1 grain), compound cathartic pills, opium pills, pills of sulphate of quinia (3 grains), sulphate of quinia, powdered Rochelle salts, sulphate zinc, blistering cerate, powdered compound extract colocynth. *Drawer* 8: 8 oz. Fowler's solution, 8 oz. aromatic sulphuric acid, 8 oz. fluid extract ipecac, 8 oz. fluid extract seneka, 8 oz. tincture chloride of iron, 8 oz. pure glycerin, blue mass, empty bottles, 8 lbs. sulphate magnesia, 8 lbs. flaxseed meal, 10 lbs. farina, 12 lbs. white crushed sugar. *Drawer* 9: 16 oz. Hoffman's anodyne, 16 oz. fluid extract ginger, 16 oz. laudanum, 16 oz. paregoric, 16 oz. chlorinated solution of soda, 16 oz. solution chloride zinc, 4 lbs. syrup of squill (part in *Drawer* No. 2), 8 oz. powdered tartaric acid, 16 oz. subnitrate bismuth, 8 oz. ground cayenne pepper. 16 oz. powdered Rochelle salt, 8 oz. alum, 8 oz. mercury with chalk, 8 oz. powdered ipecac, 8 oz. Dover's powder, 8 oz. acetate lead, 8 oz. bicarbonate potassa, 8 oz. chlorate potassa, 8 oz. iodide potassium, 8 oz. bicarbonate soda. 8 oz. nutmegs, 8 oz. powdered gum arabic, 8 oz. carbonate ammonia, 8 oz. camphor, 8 oz. powdered opium, empty bottles, 8 lbs. castile soap. *Drawer* 10: 2 tin basins (small, for dressers), 3 wash-hand basins, 2 vacant boxes for sundries, 1 metal bed-pan. *Drawer* 11: 3 lbs. simple cerate, 24 oz. sulphate cinchona, 16 oz. mercurial ointment, 1 smoothing plane, 1 saw, 1 hatchet, 1 nutmeg grater, 4 oz. white wax, 6 lbs. ground black mustard seed, 5 lbs. black tea, 1 box for sundries, 2 lbs. candles (half length). *Drawer* 12: 2 doz. planed splints, 20 gray blankets, 2 blanket cases (canvas), 8 gutta-percha bed-covers, 15 bed sacks, 15 pillow cases (white), 2 leather buckets, 1 coffee mill. The wagon also contained an amputating table, 3 box lanterns, and 2 camp stools, and four hand litters were attached outside.

[1] CONTENTS OF THE AUTENRIETH MEDICINE WAGON.—*First Case:* Tannic acid, 1 oz.; aromatic sulphuric acid, 8 oz.; powdered gum arabic, 8 oz.; stronger ether, 2 lbs.; Hoffman's anodyne, 1 lb.; alcohol, 64 oz.; alum, 8 oz.; solution of ammonia, 32 oz.; carbonate of ammonia, 8 oz.; aromatic spirit of ammonia, 4 oz.; tartar emetic, 1 oz.; nitrate of silver, 1 oz.; fused nitrate of silver, 1 oz.; subcarbonate of bismuth, 4 oz.; camphor, 8 oz.; simple cerate, 2 lbs.; cerate of cantharides, 8 oz.; resin cerate, 1 lb.; pure chloroform, 32 oz.; collodion, 4 oz.; copaiba, 16 oz.; creasote, 4 oz.; sulphate of copper, 2 oz.; fluid extract of aconite root, 4 oz.; extract of belladonna, 1 oz.; fluid extract of cinchona, aromatic, 16 oz.; fluid extract of colchicum seed, 4 oz.; compound extract of colocynth, 8 oz.; fluid extract of ipecac, 8 oz.; fluid extract of ginger, 8 oz.; tincture of chloride of iron, 8 oz.; citrate of iron and quinine, 2 oz.; solution of persulphate of iron, 4 oz.; powdered subsulphate of iron, 2 oz.; glycerin, 8 oz.; calomel, 8 oz.; blue mass, 8 oz.; mercurial ointment, 16 oz.; citrine

resecting instruments;[1] one for general and minor operations,[2] composed of knives, forceps, catheters, etc.; and a pocket case.[3] For regimental surgeons and assistant surgeons the field case[4] was issued; this contained much the same assortment of instruments as those already mentioned, but were somewhat more closely packed and more easily transported. Teeth-extracting instruments and dissecting cases were also furnished to regimental and general hospitals. Great liberality was shown in providing special instruments and appliances, and every effort was made to render the surgical equipment as perfect as possible.

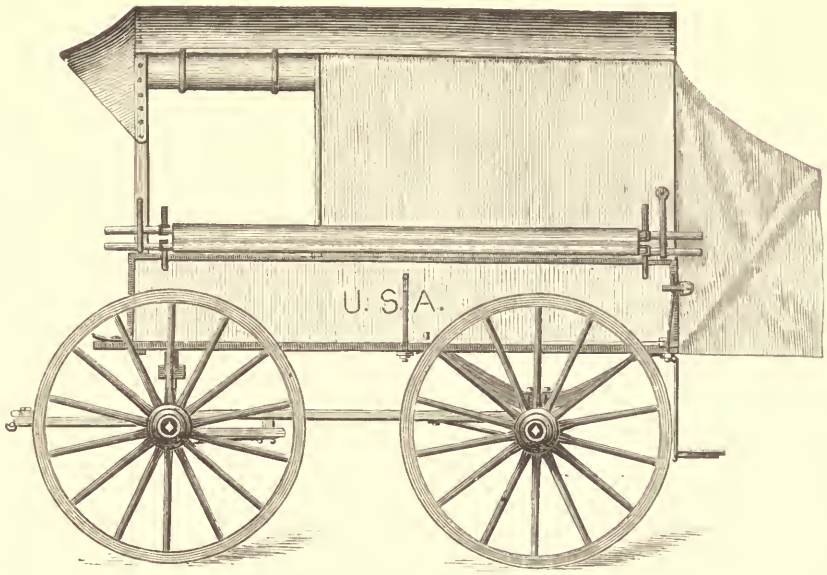

FIG. 433.—AUTENRIETH medicine wagon—side view.

At the beginning of the war it was the general custom to secure possession of buildings, such as churches, mills, and dwelling houses, for hospital accommodations; but the hygienic evils growing out of such occupancy soon led to the use of tent hospitals for the wounded, and finally, under the excellent organization of the field hospitals, tents were almost universally used by our armies in campaigns as well as in periods of inactivity. The principal tents used were the Hospital and the Sibley tent.

---

ointment, 4 oz.; Dover's powder, 8 oz.; flaxseed, 6 lbs.; flaxseed meal, 12 lbs.; morphia, ¼ oz.; olive oil, 2 qts.; castor oil, 4 qts.; oil of turpentine, 1 qt.; croton oil, 1 oz.; powdered opium, 8 oz.; tincture of opium, 16 oz.; paregoric, 16 oz.; pills of camphor (2 gr.) and opium (1 gr.), 12 doz.; compound cathartic pills, 16 doz.; pills of compound extract of colocynth (3 gr.) and ipecac (½ gr.), 16 doz.; opium pills, 10 doz.; sulphate of quinine (3 gr.) pills, 12 doz.; chlorate of potassa, 8 oz.; acetate of lead, 8 oz.; bicarbonate of potassa, 8 oz.; permanganate of potassa, 32 oz.; iodide of potassium, 8 oz.; sulphate of quinine, 8 oz.; soap, 8 lbs.; syrup of squill, 3 lbs.; powdered black mustard, 9 lbs.; bicarbonate of soda, 8 oz.; solution of chlorinate of soda, 32 oz.; Rochelle salt, 16 oz.; sweet spirit of nitre, 2 lbs.; solution of chloride of zinc, 1 lb.; sulphate zinc, 1 oz.; sulphate cinchona, 2 oz.; arrow root, 10 lbs.; extract of beef, 16 lbs.; brandy, 6 qts.; farina, 10 lbs.; nutmegs, 4 oz.; sugar (white, crushed), 15 lbs.; extract of coffee; black tea, 10 lbs.; whiskey, 6 qts.; patent lint, 6 lbs.; scraped lint, 2 lbs.; roller bandages (assorted), 32 doz.; suspensory bandages, 8. The wagon also contained surgical instruments, books, and stationery, prescription furniture and utensils, bed-pans, urinals, tow, coffee mill, rubber buckets, tin basins, wash-hand basins, blankets, gutta percha bed-covers, lanterns, and a hatchet. The medicines were arranged in slides; the hospital stores, dressings, furniture, utensils, etc., were arranged in drawers or on shelves.

[1] The *Capital Operating Case* contained: 2 amputating knives (one long, one medium), 2 catlings (one long, one medium), 4 scalpels, 1 cartilage knife, 1 capital saw (long, bow, two blades), 1 metacarpal saw, 1 chain saw, 1 Hey's saw, 1 trephine (conical), 1 trephine (small crown), 1 bone forceps (Liston's long, sharp, spring handle), 1 bone forceps (broad edged, slightly curved, spring handle), 1 bone forceps (gnawing, spring handle), 1 bone forceps (sequestrum, spring handle), 1 artery forceps, 1 artery needle, 1 artery needle key, 12 surgeon's needles, 1 tourniquet screw with pad, 1 tenaculum, 1 scissors, 1 chisel, 1 gouge, 1 mallet, 4 drills (with one handle), 2 retractors, 1 raspatory, 1 elevator, 1 brush, 12 yards suture wire (iron), ¼ oz. ligature silk, ½ oz. wax, 1 mahogany case (brass bound, slide catch), 1 leather pouch.

[2] The *Minor Operating Case* contained: 1 amputating knife, 3 scalpels, 2 bistouries, 1 hernia knife, 1 finger knife, 1 artery forceps, 1 ball forceps, 1 gullet forceps, 1 dressing forceps, 1 dissection forceps, 1 artery needle, 1 artery needle key, 12 surgeon's needles, 1 tenaculum, 2 scissors, 1 trocar and canula, 1 Belloc's canula, 1 bullet probe, 1 director, 1 cutting pliers (small), 6 steel bougies (silvered, double curve, Nos. 1 and 2, 3 and 4, 5 and 6, 7 and 8, 9 and 10, 11 and 12), 3 silver catheters (Nos. 3, 6, and 9), 6 gum-elastic catheters (Nos. 1, 3, 5, 7, 9, and 11), 24 suture pins (silvered), 6 yards suture wire (iron), ¼ oz. ligature silk, ½ oz. wax, 1 mahogany case (brass bound, slide catch), 1 leather pouch.

[3] The *Pocket Case* contained: 1 scalpel, 3 bistouries, 1 tenotome, 1 gum lancet, 2 thumb lancets, 1 razor (small), 1 artery forceps, 1 dressing forceps, 1 artery needle, 6 surgeon's needles, 1 exploring needle, 1 tenaculum, 1 scissors, 1 director, 3 probes, 1 caustic holder, 1 silver catheter (compound), 6 yards suture wire (iron), ¼ oz. ligature silk, ½ oz. wax, 1 Russia leather case.

[4] The *Field Case* contained: 2 amputating knives (one long, one medium), 2 catlings (one long, one medium), 3 scalpels, 2 bistouries, 1 hernia knife, 1 finger knife, 1 capital saw (long, bow, two blades), 1 metacarpal saw, 1 Hey's saw, 1 trephine (conical), 1 bone forceps (broad edged, slightly curved, spring handle), 1 bone forceps (sequestrum, spring handle), 1 artery forceps, 1 ball forceps, 1 dressing forceps, 1 dissection forceps, 1 artery needle, 1 artery needle key, 12 surgeon's needles, 1 tourniquet screw with pad, 1 tenaculum, 2 scissors, 2 retractors, 1 trocar and canula, 1 raspatory, 1 elevator, 1 brush, 1 bullet probe, 1 director, 6 steel bougies, silvered, double curve (Nos. 1 and 2, 3 and 4, 5 and 6, 7 and 8, 9 and 10, 11 and 12), 3 silver catheters (Nos. 3, 6, and 9), 6 gum-elastic catheters (Nos. 1, 3, 5, 7, 9, 11), 12 yards suture wire (iron), ¼ oz. ligature silk, ½ oz. wax, 1 mahogany case (brass bound, slide catch), 1 leather pouch; pocket case the same as allowed to staff surgeons.

The hospital tent[1] in use previous to the war was 24 feet in length, 14 feet 6 inches in breadth, and 11 feet 6 inches high; it was bulky, heavy, and difficult to pitch in windy weather. By the action of an army board in 1860 its size was reduced, the general form being retained. Its general appearance will be seen in FIG. 434, and its dimensions were: length 14 feet, breadth 14 feet 6 inches, height 11 feet (centre), with a wall 4½ feet, the whole covered with a "fly" 21 feet 6 inches by 14 feet. The weight of this tent, including its poles and pins, was 217 pounds. Each tent had at one end a lapel to admit of two or more tents being joined and thrown into one ward. Each hospital tent was designed to accommodate comfortably eight patients. This tent has been found in practice to answer every necessary purpose. By the Army Regulations three hospital tents were assigned to each regiment, also one Sibley tent and one common wedge tent. The Sibley tent (FIG. 435) is conical in shape, 18 feet in diameter at base and 12 feet high, with an opening at the apex, to which is fitted a hood which may be closely fitted or removed at pleasure. The absence of any wall renders it inconvenient and illy adopted to hospital purposes, and the want of a fly renders it almost intolerable on account of heat in midsummer, while the centre pole curtails the available space and interferes with the free movements of the medical officers and attendants. It was not used to any very great extent for hospital purposes. The wedge tent was still less adapted to hospital purposes though found convenient as an adjunct to field hospitals. The hospital tent "fly" alone was found to answer an admirable purpose in sheltering the wounded in mild weather or when it was inconvenient or impracticable to pitch the entire tent.

FIG. 434.—Regulation hospital tent.

FIG. 435.—Sibley tent.

Surgeon A. P. Meylert, U. S. V., treated about eighteen hundred (1,800) patients in a field hospital of the Army of the Ohio constructed of tarpauling, such as was used by the Quartermaster's Department for covering stores and forage, and remarks: "The chief cause of success in this hospital, I believe, was in the mode of shelter adopted. The difficulty in obtaining quarters for the sick and wounded, which in the outset I regarded as the greatest possible calamity, was no doubt of the utmost advantage, since it led to the adoption of those cool, clean, and airy wards, in which I am satisfied the patients improved more rapidly and surely than in either wall or hospital tent or in ordinary buildings. Whenever it was practicable, board floors were placed in the tents, resting on sleepers placed directly on the ground. A trench from 6 to 8 inches in depth, dug around the base, and loose earth thrown around the lower edge of the tent wall in cold weather, completed the arrangement."

[1] In October, 1859, a board of medical officers, consisting of Surgeons C. A. Finley, R. S. Satterlee, C. S. Tripler, J. M. Cuyler, and Assistant Surgeon R. H. Coolidge, had recommended for the army the following allowance of tents for the sick and wounded and their attendants: For one company, 1 Sibley tent and 1 common tent; for three companies, 1 hospital tent, 1 Sibley tent, and 1 common tent; for five companies, 2 hospital tents, 1 Sibley tent, and 1 common tent; for ten companies, 3 hospital tents, 1 Sibley tent, and 1 common tent.

The bedsteads used in the hospital tents were cots of a light frame-work of stout wood, provided with four folding legs and furnished with a jointed support near the head. The whole frame-work was covered with sacking, and throughout the war proved a most useful and satisfactory hospital cot. It was light, strong, easily transported, and was comfortable to the patient.

Various modes were employed for heating hospital tents in the field. Wood-burning stoves were largely used, their chief objection being the difficulty of transportation. The plan which was most generally in vogue, particularly in the Army of the Potomac, and which gave the utmost satisfaction, was that known as the California plan. A pit was dug about two-and-a-half feet deep outside the door of the hospital tent; from this a trench passed longitudinally through the tent, terminating outside its farther or closed extremity. At this point a chimney was formed by barrels placed one upon the other, or by some other simple plan. The joints and crevices of this chimney were cemented with clay. The trench in the interior of the tent was roofed over with plates of sheet-iron issued for that purpose by the Quartermaster's Department. A fire was built in the pit, and the resulting heat, radiating from the sheet-iron plates, kept the interior of the tent warm and comfortable even in the coldest weather. In the western armies, in the trench in the interior of the tent, railroad iron was placed in regular layers and covered with iron plates when possible to procure them, or with stone slabs. Occasionally funnel-shaped stoves, open at the bottom, resting upon the ground, and provided with a short pipe, were used. These were, however, objectionable. The wood fire burned out rapidly, and although an intense heat was created while it lasted, after its extinguishment the atmosphere soon chilled, exposing the men to rapid and uncomfortable changes of temperature.

From an examination of the records and reports in this office it would appear that the first regular tent field hospital was organized during the battle of Shiloh, April, 1862, by Dr. B. J. D. Irwin, U. S. A., Medical Inspector of the 4th Division, Army of the Ohio. His interesting description is here given: "During the military movements of troops during the battle of Shiloh," Dr. Irwin says, "one of the operating hospitals was moved forward to a deserted farm-house situated on an open level piece of unbroken ground. The presence of a spring of cool potable water and the nearness of the building to a branch of the creek were advantages that were promptly recognized, and but a short time elapsed ere these valuable desiderata were utilized in providing shelter and other comforts for the large number of wounded of our own division and those disabled on that part of the field in the preceding day's conflict, pertaining to both of the contending parties, left on the field without assistance some twenty-four to thirty-six hours. The proximity of this field hospital to the recaptured camp of a division of our troops defeated and made prisoners the preceding day, suggested the utilization of the abandoned tents for the benefit of the wounded; and as soon as the battle ceased the hospital tents, commissary tents, and wall tents pertaining thereto were accordingly taken possession of, and in a short space of time were removed to and pitched in regular order on the level ground by which the house was surrounded. The building afforded an operating room, dispensary, office, kitchen, and dining-room. Long into the night the ambulances continued to bring in the wounded, who, after receiving the necessary professional attendance, were made as comfortable as possible by being supplied with an abundance of warm food, good bedding, and shelter from the inclement weather. Next day the hospital camp was enlarged so as to accommodate some 300 patients, and the tents were systematically arranged; all bedsteads, cots, bedding, cooking and messing utensils, hay and

straw found in the abandoned camp were taken possession of, and on the evening of the 8th the Division Medical Purveyor reached us with our medical supplies and hospital stores. By this time the hospital had assumed the proportions and discipline of a well regulated army camp, arranged with a view to meet the special wants of those for whom it had been established. Some mattresses were secured, and the bed-sacks, filled with hay and straw, were placed on cots, bedsteads, or improvised bunks, so that almost every patient was provided with comfortable sleeping accommodations. A suitable number of attendants of each class was detailed for duty in the establishment, which was placed under the charge of Surgeon Menzies, 1st Kentucky Volunteer Infantry, so that the invalids were promptly and regularly supplied with abundance of properly prepared nutritious food, and even a fair supply of extra diet and delicacies were served to the inmates requiring special attention. It soon became manifest that the wounded in this improvised field hospital were better provided for and more comfortable in every way than those who were moved aboard the hospital transports. * * * In illustration of how the efforts made to ameliorate the condition of the wounded were appreciated the following official communication was published, viz:

"'HEADQUARTERS FOURTH DIVISION, ARMY OF THE OHIO,
FIELD OF SHILOH, *April* 12, 1862.

"Col. J. B. FRY,
Assistant Adjutant General, Chief of Staff.

"'SIR: I desire to call the especial attention of the General commanding this Army to the admirable hospital accommodations adopted by Dr. Irwin, U. S. A., Medical Inspector of the Division, during the battle of the 7th inst. They will be found as nearly perfect as the circumstances would allow. The wounded in the Division did not suffer from the inclement weather; they were all promptly sheltered and cared for. I beg to recommend Dr. Irwin to the favorable consideration of his superiors.

"'Very respectfully,
(Signed) "'W. NELSON,
"'*Brigadier General.*'

"Thus was established the *first* tent field hospital of any magnitude for the reception and treatment of the wounded on the field of battle. In the movements of the army following Shiloh and culminating in the siege of Corinth, Miss., the utility of large field hospitals was recognized, and soon developed into a system which became general in the combined armies engaged in the investment of that place. * * * Further experience in the treatment of the sick and wounded under canvas demonstrated the many great advantages possessed by such hospitals over those established in churches, houses, and other structures temporarily used as hospitals, such as the wooden and iron huts used by the allied armies in the Crimea, or those established in large buildings, especially when not constructed in accordance with modern sanitary science. Numerous tent hospitals of much greater capacity were established and kept in successful operation during the last two years of the war, it having been satisfactorily shown that the wounded who were treated under canvas did better in every way, and recovered sooner than those treated in the large permanent hospitals."

The consideration of the construction, organization, and administration of permanent or general hospitals is deferred to the Third Medical Volume of the Medical and Surgical History of the War.

LIBRARY OF THE UNIVERSITY OF CALIFORNIA

CHAPTER XV.

TRANSPORTATION OF THE WOUNDED.

The first removal of the wounded from the battle-field was generally effected by means of hand litters. The number of litters issued during the war exceeded fifty thousand[1] (50,000). From the Purveyor's Office at New York, Brigadier General R. S. Satterlee reports that from April 1, 1861, to August, 1865, sixteen thousand eight hundred and seven (16,807) hand litters were issued. At the Medical Purveyor's Depot at Louisville, from November, 1863, to August, 1865, seven thousand and ninety-eight (7,098) hand stretchers were issued, and Surgeon D. L. Magruder, U. S. A., estimated that four thousand seven hundred and thirty-two (4,732) had been given out before November, 1863. The Medical Purveyor's Office at Philadelphia issued, from January, 1863, to August, 1865, five thousand five hundred and forty-eight (5,548), and the Office at New Orleans, from September, 1864, to the end of the war, eight hundred and thirty-five (835) stretchers.[2]

In the beginning of the war the Satterlee, or U. S. Regulation litter (FIG. 436), was supplied to the regiments. It weighed twenty-four and one-half pounds and was twenty-seven inches wide. The canvas consisted of two pieces, five feet ten inches long, sewed in the centre with a flat seam, and with a hem on either side seven and one-half inches wide, through which the poles were passed; there was an inch and a half hem on each end; on one end were three tarred rope loops to put over the pins on the cross-bar,

FIG. 436.—SATTERLEE or Regulation hand litter.

[1] The Records of the Property Division of the Surgeon-General's Office show that from 1861 to 1865 fifty-two thousand four hundred and eighty-nine (52,489) litters of various manufacture were purchased and issued to the troops.

[2] Extemporaneous modes of conveying wounded from the field of battle can only be briefly alluded to. Stout sticks or muskets may be passed through the sleeves of a coat or rolled into the edges of blankets and a litter thus be formed. Hurdles, gates, or ladders, with blankets or straw thrown over them, have made useful stretchers. Poles interlaced with ropes or telegraph wire have been found to answer the purpose of a litter. The editor was once obliged to transport a soldier, wounded in the abdomen, a distance of twelve miles along the narrow bed of a creek filled with boulders and obstructions: "I was fortunate enough to find two ash saplings which, with a blanket stretched across, made an improvised litter, on which my patient was borne by relays of men with comparative ease and comfort. At another time a man belonging to a small detachment sent out from a scouting party was wounded in the leg by the accidental discharge of a musket. Finding it impossible to place the man on horseback, and unsafe to detach a small party to seek the main command, his comrades carried him a distance of about three miles by forming a seat with their hands and arms similar to the chairs made by children in their games (Fig. 437). During the late war I saw a soldier who had been wounded at some distance from his command conveyed to a place of safety by laying him prone across a saddle, the stirrup of one side being sufficiently lengthened to afford support for one foot. The horse with his burden was then led quite a distance. I am familiar with another instance where a man, badly wounded, was conveyed about a three-days' journey in a cot or hammock formed by securing a blanket to two lariat-ropes; the ends of the ropes were gathered and carried by his comrades on horseback. All military surgeons know of instances where wounded men have been carried from the battle-field on muskets with an overcoat laid upon them for a bed. Under the urgent demands of necessity the fruits of ingenuity are sure to come to the rescue." (See *Circular* No. 9, *On the Transport of Sick and Wounded by Pack-Animals*, Washington, 1877, p. 27.)

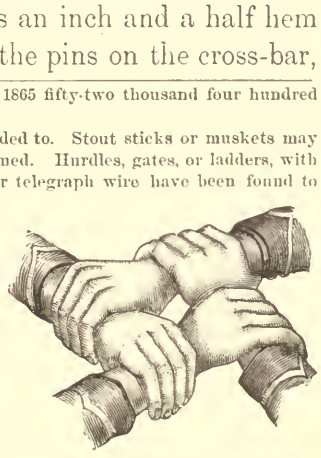

FIG. 437.—Seat made by clasping hands.

and two five-inch drilling loops for pulling the canvas over the poles; at the other end were three eyelet-holes, with a piece of rope three feet long and spliced into one of the holes for fastening the canvas to the pins on the other cross-bar. The poles were made of seasoned red ash, were one and one-half inches in diameter and eight feet nine inches long. Sixteen inches from either end of the poles were wrought-iron bands three-sixteenths of an inch thick and three-fourths of an inch wide, and riveted to the poles as shoulders for the cross-bars to strike against. The cross-bars weighed six and one-fourth pounds; they were made of seasoned white ash, one and one-half inches thick by twenty-four inches long. A piece of wrought-iron, six feet long by one inch wide and one-fourth of an inch thick, was so curved as to form the legs[1] and sockets on either end of the wooden cross-bar for the poles to pass through, and was fastened by two rivets, one at each end; the pin in the centre, on which the canvas was looped, was used as a third. The three pins in each cross-bar were made of half-inch iron, and projected one inch, with heads to keep the loops from slipping off. The shoulder straps weighed one and one-half pounds, were made of leather two inches wide, five feet eight inches long, with a three and one-half inches loop at one end and a buckle at the other end for adjustment on the handles of the stretcher. One objection to the Satterlee litter was its bulk, which seriously interfered with its conveyance in large numbers.

The Halstead[2] litter, a stretcher of lighter and more compact pattern (FIG. 438), soon superseded the Satterlee. It weighed twenty-three and three-fourths pounds and was twenty-three and one-half inches wide; the length of the canvas (unbleached) was five feet eleven inches, being fastened on the outer side of the rave with six-ounce tacks. The poles were made of seasoned white ash, eight feet long and one and five-sixths inches square, with thirteen inches at one end and twelve inches at the other, extending beyond the canvas, and rounded off for handles. The legs, which were also made of seasoned white ash, were fourteen and one-half inches long, one inch thick, one and seven-eighths inches wide at the top, and tapering to one and three-eighths inches at the bottom. They were fastened to the poles with screw bolts, washers under the heads of the bolts, and rivets through the upper end of the legs to prevent them from splitting. The braces to hold the stretcher open, one (on the under side) at either end, consisted of two pieces of wrought-iron one inch wide by three-eighths of an inch thick; one piece was fifteen inches and the other twelve inches in length, hinged in the centre of the stretcher, the longer one overlapping the shorter three and one-half inches, and, when open, shutting on a bolt or pin, forming a stiff shoulder for the hinge and preventing the stretcher from accidentally closing. The braces were fastened on with heavy screws, with pieces of common hoop iron underneath the braces to prevent them from wearing the wood. The shoulder straps weighed eight ounces, and were made of striped cotton webbing two and one-half inches wide by fifty inches long, with a five-inch loop at one end and a leather strap twenty-two and one-half inches long by one and one-sixth inches wide, with buckle, at the other end to loop around the handles of the stretcher at any length desired. A hair pillow covered with canvas accompanied this stretcher, which

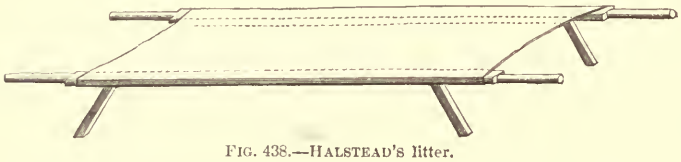

FIG. 438.—HALSTEAD'S litter.

[1] Professor LONGMORE in his *Treatise on the Transport of Sick and Wounded Troops*, London, 1869, p. 129, has probably mistaken the iron feet for yoke pieces, as he speaks of the absence of feet in the litter.

[2] In the preliminary report, *Circular* No. 6, S. G. O., 1865, p. 81, this litter is erroneously called the Smith hand litter; the litter there designated as the Halstead litter was a stretcher issued by the Sanitary Commission. It is to be regretted that these errors have misled Professor LONGMORE, who in his excellent *Treatise on the Transport of Sick and Wounded Troops*, p. 141, reproduced the wood-cuts from *Circular* No. 6.

gave great satisfaction, and out of the litters (16,807) issued by the New York Purveying Depot twelve thousand eight hundred and sixty-seven (12,867) were of this pattern.

Of the litter shown in FIG. 439 and known in New York as the Sanitary Commission litter, few were issued; it was too fragile for the hard usage of actual warfare.

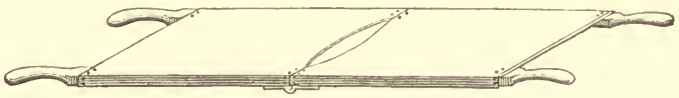

FIG. 439.—Sanitary Commission litter.

A drawing of the litter used in the Confederate armies is shown in FIG. 440, and has been copied from Chisolm.[1] Its construction was very simple and, with the exception of the mode of securing the duck cloth, or sacking, to the frame, needs no explanation: "A groove three-quarters of an inch wide and five-eighths of an inch deep is cut out in the length of the frame. The cloth is tacked in this and secured by a lath which fits accurately the groove and which is nailed in, covering the cloth. The tension upon the cloth is not borne by the tacks, but is uniformly supported by the entire lath, and therefore never rips off."

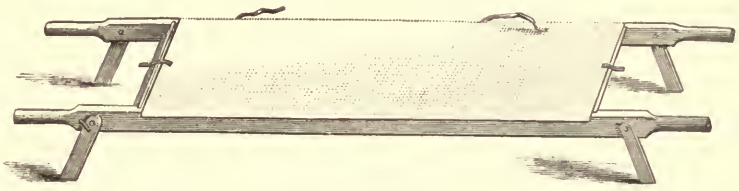

FIG. 440.—Confederate litter.

A litter to be used as a bedstead was proposed by Assistant Surgeon Henry S. Schell, in 1862, in a letter to Medical Inspector Vollum, U. S. A.: "I beg leave to suggest that the hand litter at present in use be somewhat modified, so that it may be arranged as a bedstead in the hospital tent when it is desirable to have a large number of beds quickly made up. It generally takes a day, perhaps more, to prepare bedsteads, or rather to build them, so that they may be elevated from the damp and uneven surface of the ground. The present stretcher cannot be used to make two rows of beds, with a passage from door to door between them in the usual manner, because of its length. The litter (FIGS. 441, 442) which I would propose is constructed of two parallel bars, each six feet two inches long, connected by a strong canvas, and separated by a jointed iron rod about six or eight inches from each end, somewhat similar to those on the litter now in use. To the ends of each of the parallel wooden bars a shorter one, ten inches long, is joined by a strong hinge placed underneath. This latter bar constitutes the handle when used as a stretcher, or the leg when used as a camp bedstead. It is retained in the upright position by a short iron stay, as seen in the figure. I have long felt the want of such an arrangement when arriving in camp and wishing to pitch the hospital tent immediately. The hinge will be found to last much longer than the canvas. As each ambulance carries two stretchers, a hospital may be improvised from these very readily."

In the last year of the war an order was issued for the construction of a form of litter[1] on wheels (FIG. 443), similar to one used advantageously in the Danish war of 1864, but there are no reports that indicate its practical utility.

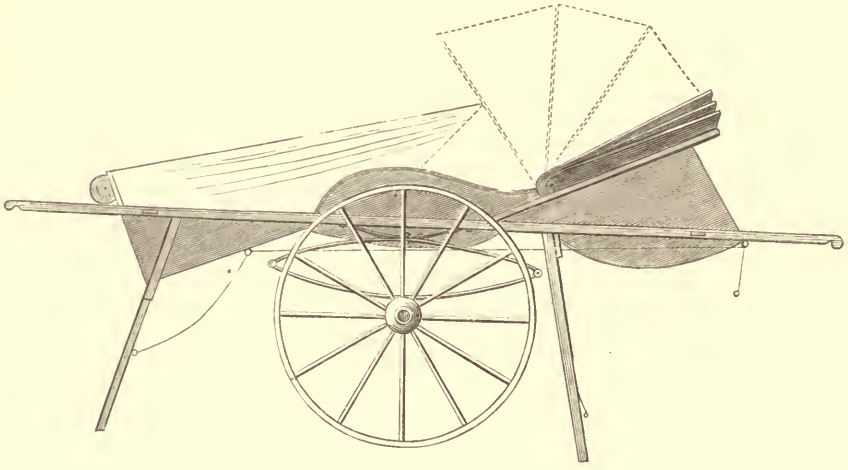

FIG. 443.—Hand-litter carriage—scale ½ inch to the foot.

The modes of carrying wounded men on horse or mule litters during the war have been fully described in *Circular* No. 9, Surgeon General's Office, March 1, 1877, and we cannot do better than to reproduce, with a few additional remarks, the account given there by the author, the late Surgeon George A. Otis, U. S. Army:

"In the Revised Regulations for the Army of the United States for 1861, Paragraph 1298 reads: 'Horse litters may be prepared and furnished to posts whence they may be required for service on ground not admitting the employment of two-wheeled carriages; said litters to be composed of a canvas bed similar to the present stretcher, and of two poles, each sixteen feet long, to be made in sections, with head and foot pieces constructed to act as stretchers to keep the poles apart.' There is no record that these litters were used during the war.[2]

"During the progress of the late war in this country a number of persons, actuated by motives of patriotism, humanity, or interest, devised and brought to the notice of the War Department forms of conveyance for the sick and wounded in localities impracticable for wheeled vehicles, that were represented as improvements upon existing patterns. Several of these were apparently suggested by the descriptions of Delafield[3] and McClellan[4] of the horse litters and cacolets they had observed in the Crimea. In October, 1861, W. C. H. Waddell forwarded to Secretary Cameron a proposal to construct cacolets and litters for army use, accompanied by drawings (FIGS.

[2] Professor T. LONGMORE, in his excellent *Treatise on the Transport of Sick and Wounded Troops*, London, 1869, p. 292, thus refers to this form of litter: "It is necessary to notice another form of sick-transport litter issued for use in the early part of the late war in the United States, in which, instead of two litters being suspended across one horse or mule, one litter was suspended between two horses. This is a very ancient form of litter in Europe. Frequent notices of it occur, showing its common use on occasions of state and ceremony, as well as its employment for the carriage of sick persons, in the records of our own country prior to the introduction of coaches. It seems curious that its use should have been revived in modern times in America." In a note it is added: "This form of litter is referred to as late as the reign of Charles II. A quotation introduced into the first volume of Knight's London, pp. 24 and 25, mentions that 'Major General Skipton, coming in a horse-litter to London when wounded, as he passed by the brew house near St. John street, a fierce mastiff flew at one of the horses and held him so fast that the horse grew mad as a mad dog: the soldiers were so amazed that none had the wit to shoot the mastiff; but the horse-litter, borne between the two horses, tossed the major-general like a dog in a blanket.'"

[3] *Report on the Art of War in Europe in* 1854, 1855, *and* 1856, *by Major* RICHARD DELAFIELD, *Corps of Engineers, from his Notes and Observations made as a member of a "Military Commission to the Theatre of War in Europe,"* Washington, 1860.

[4] *Report of the Secretary of War, communicating the Report of Captain* GEORGE B. MCCLELLAN *(First Regiment United States Cavalry), one of the officers sent to the Seat of War in Europe in* 1855 *and* 1856, Washington, 1857.

446, 447) copied from Delafield's report, and suggested some trivial modifications. In November, 1861, Mr. G. Kohler offered to furnish mule litters and chairs of patterns imitated from those used in the Crimea. In July, 1862, three hundred of these litters were purchased. In April, 1862, Surgeon Glover Perin, U. S. A., and Assistant Surgeon Benjamin Howard, U. S. A., reported to Surgeon General C. A. Finley the results of their inspection of cacolets and litters devised by Mr. Charles Proal, of Louisville.[1] Newspaper descriptions, almost textually quoted from Delafield's report, with figures of these appliances, were transmitted. Mr. Proal claimed to have improved upon the French patterns by diminishing the weight and cost of construction. Messrs. Lawrence, Bradley & Pardee, of New Haven, Connecticut, in 1861, applied for a patent for a cacolet of cumbrous pattern, weighing 131 pounds. The chairs could not be detached from the saddle. A sample, figured in the adjoining wood-cut (FIG. 445), was sent, in 1867, to the Army Medical Museum, and is numbered 824 in Section VI. It combines, in an unusual degree, the undesirable qualities of weight, weakness, and inconvenience. On September 25, 1862, a board of officers of the Quartermaster's Department examined cacolets submitted by Dr. Slade Davis, and reported[2] that, as compared with others that had been purchased for the service, the only advantage of this form of cacolet was its lightness. It was thought that those already on hand were as light as was consistent with the requisite degree of strength. Mr. E. P. Woodcock,[3] of New York, in November, 1863, patented a pack-saddle with wooden outriggers from the pommel and cantle for the suspension of litters. By securing litters to the projecting parts by straps, and protecting the sides of the animal by pads, it was designed to carry two patients in the recumbent position. This contrivance was exhibited by the United States Sanitary Commission at the Exposition in Paris in 1867, but met with no more approval abroad than at home. Mr. J. Jones,[4] of New York, in December, 1862, proposed to the Surgeon General of the Army a mule litter for carrying two persons either in a sitting or recumbent position, the litters being designed to serve also as efficient hand stretchers or hospital-beds. The 'exceeding lightness, strength, and simplicity' of these conveyances were insisted on. The saddle with

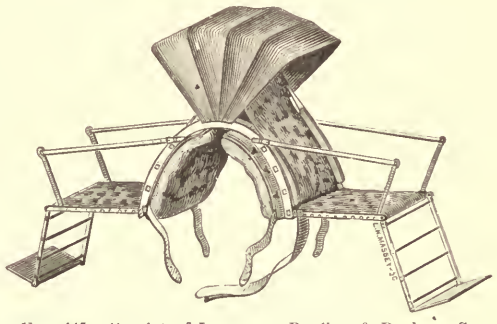

FIG. 445.—Cacolet of Lawrence, Bradley & Pardee. *Spec.* 824, SECT. VI, A. M. M.

[1] Extract from a communication to Surgeon General C. A. FINLEY, by Surgeon G. PERIN and Assistant Surgeon B. HOWARD, dated Louisville, April 2, 1862: "The undersigned would respectfully state that Mr. CHARLES PROAL, of this city, has submitted to our inspection a saddle ambulance, which has been fairly tested by us in the open field. Its chief excellences, compared with other saddle ambulances, are that it is lighter, is more easily adjusted, and combines both the litter and the chair, both of which can be packed away in a very small compass when the pack-saddle to which they belong is required for other purposes. The weight of the entire ambulance, with saddle, etc., is about seventy-four pounds, that of the French being about one hundred and forty-two pounds. The mode of adjustment is such that two litters, two chairs, or one chair and one litter, can be used at the same time, at discretion, each of which may be affixed to or detached from the saddle, while the patient remains undisturbed. The harness appears to be very complete, the breeching and breast-band preventing motion backward or forward, while the surcingle, by being attached to the bottom of each chair or litter, prevents either undue oscillation or shifting, which would be otherwise consequent upon any inequality in the weight of the two patients being carried . . . The price of the ambulance and appurtenances completed is about $50."

[2] A board of officers, consisting of Colonel D. H. RUCKER, Quartermaster, Captain J. J. DANA, A. Q. M., and Captain E. E. CAMP, A. Q. M., was convened at Washington, September 25, 1862, to "examine a cacolet to be presented for inspection by Dr. SLADE DAVIS, and to report its opinion of the cacolet, as compared with other patterns which have been purchased for the service. The board reported that "in their opinion the cacolet presented by Dr. SLADE DAVIS possessed an advantage over those furnished by Mr. KOHLER (three hundred in number, all of which are now on hand) in lightness only. Those made by Mr. KOHLER are constructed in a strong and desirable manner, and are as light as is consistent with the requisite degree of strength. No call has yet been made, either for those first purchased or for those furnished by Mr. KOHLER, which cost $21,000. We would not recommend the purchase of an additional number from any source."

[3] Compare LONGMORE (*Treatise on the Transport of Sick and Wounded, etc., op. cit.*, p. 290): Subject-matter, *Index of Patents for Inventions*, Washington, 1874, Volume III, p. 1232; and SÉRURIER (*Conférences Internationale des Sociétés aux Blessés Militaires des Armées de Terre et de Mer, tenues à Paris*, en 1867, T. I, p. 47).

[4] Manuscript Records of War Department for 1862.

two litters, girths, bridle, and other appurtenances weighed only 62 pounds, and could, probably, be reduced to 60 pounds. In September, 1863, a board of medical officers was convened in Washington to examine into the merits of an adjustable ambulance and pack-saddle, 'submitted by Spencer, Nichols & Co.' Lightness, strength, simplicity, efficiency, adjustability, and cheapness were the merits claimed for this contrivance.[1] Shortly afterward (December 1, 1863) another medical board assembled in Washington to inspect and report on a mule litter submitted by Messrs. Pomeroy & Co., which was found to possess some good and some objectionable features.[2] In addition to these essays in invention, cacolets and litters were submitted to the Quartermaster's Department that purported to be constructed simply in accordance with drawings in General Delafield's report.[3] August 20, 1861, Messrs. Lutz & Bridget, harness-makers, furnished twenty such sets, with pack-saddles and harness. These drawings, which are copied, of a reduced size, in FIGS. 446 and 447, though prepared by so distinguished an artist as Professor Weir, do not accurately represent the mechanical details of either the French or British Crimean litters and cacolets, and the ambulance equipments made in imitation of them did not prove to be of utility. Early in the war, however, probably as early as May, 1861, the Quartermaster's Department had purchased a number of cacolets and mule litters of the pattern used in the French army, and in July, 1861, engaged Tiffany & Co., of New York, to construct others, and employed a French agent to give instruction in the

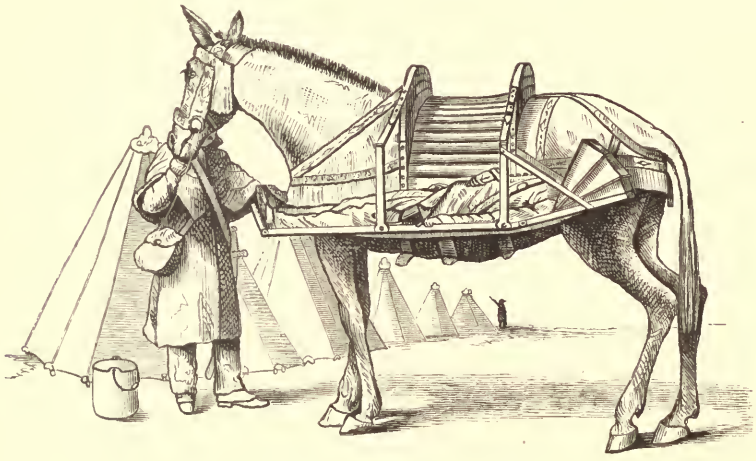

FIG. 446.—British Crimean mule litter. [After WEIR.]

[1] The board, consisting of Surgeon T. H. BACHE, U. S. V., Surgeon C. ALLEN, U. S. V., and Assistant Surgeon W. MOSS, U. S. V., reported, September 16, 1863: 1. That the cacolets weighed 55½ pounds, and the saddle-girths and other equipment 38 pounds; 2. The saddle-tree was jointed so that by turning screws it could be adapted to animals of different sizes; 3. As to simplicity, the saddle was provided with projecting crane-like supports of hickory, covered with raw-hide, which were connected either with a flat framework of hickory for packs, or with litters for patients; 4. As to strength, the saddle easily sustained two barrels of flour; but when two soldiers, one of them a heavy man, mounted on the litters there was a "slight yielding;" but the board considered the litters "strong enough to bear any load that a horse or mule could carry." Finally, the board considered the pattern submitted as "comfortable as such a conveyance can be made."

[2] The board consisted of Medical Inspector J. M. CUYLER, U. S. A., Surgeon O. A. JUDSON, U. S. V., and Assistant Surgeon C. A. MCCALL, U. S. A. The report is unaccompanied by a description or drawing of the conveyance, but states that it was simple in construction, with unusual capacity for providing for the comfortable carriage of two wounded men. Some modifications were suggested, such as strengthening the attachments of the litters by substituting chains for straps; of supplying means for rendering their framework rigid, so that they might be used temporarily as stretchers; of arranging that they might be detached from the saddle; of having rings and hooks for attaching necessary articles to the pack-saddle, and particularly a vessel for water. The board was unwilling to decisively approve of the conveyance until these alterations had been effected and a trial in actual service had been successfully made.

[3] DELAFIELD (R.) (*Report on the Art of War in Europe*, 4-to, Washington, 1860, p. 73) makes the following observations on mule litters and cacolets: "The requisites for an ambulance should be such as to adapt it to the battle-field, among the dead, wounded, and dying; in plowed fields, on hill-tops, mountain slopes, in siege batteries and trenches, and a variety of places inaccessible to wheel carriages, of which woods, thick brush, and rocky ground are frequently the localities most obstinately defended, and where most soldiers are left for the care of the surgeons. These difficulties were felt in a great degree by all the armies allied against Russia in the siege of Sebastopol, and the consequence was that the English, French, and Sardinian armies adopted finally, in part or altogether, *pack-mules carrying litters or chairs*. The careful and sure-footed mule can wind its way over any road or trail, among the dead, dying, and wounded on any battle-field, as well as in the trench and siege battery. It required but suitable arrangements to support the wounded from the mule's or horse's back to attain the desired object, and this the allied armies finally accomplished and put in practice. The merit of the plan renders it worthy our consideration, particularly so in our Rocky Mountain and other distant expeditions." Further on he remarks: " . . . I witnessed the transport of one hundred and ninety-six sick and wounded French soldiers, with their arms, accoutrements, and knapsacks, on the route from the Tchernaya to Kamiesch Bay, on these litters and chairs. Fifty-two of them were on twenty-six mules in the horizontal litters, and one hundred and forty-four seated in chairs on seventy-two other mules. A driver was provided for every two mules or four wounded men. The appearances, with such an examination as I gave the whole equipment, were so favorable as to recommend it for trial in our service. To make the system better understood I annex two additional figures (FIGS. 446 and 447), showing the animal, the equipment, and position of the soldier, for which compilation and drawing I am indebted to Professor WEIR."

use of these cacolets and litters, and purchased animals specially adapted for their transport. The Quartermaster General has remarked that these horses and mules were gradually appropriated as draft animals, and that the litters and cacolets were, for the most part, condemned as unserviceable. The French litters and cacolets were what is known as the old pattern, such as the French used in Algeria and the Crimea. They are figured in the surgical report in *Circular* 6, S. G. O., 1865, at page 82. Surgeon General Longmore correctly observes (*op. cit.*, p. 291) that 'the same drawings may also be seen in Chapter XX of M. Legouest's *Traité de Chirurgie d'Armée*, Paris, 1863, pp. 968–9.' I ventured to copy the drawings because they well represented the identical cacolets and litters issued in our army, and through an inadvertence, which must be conceded to be unusual in me, I neglected to acknowledge my indebtedness to my honored friend and master. I trust this explanation will convince him and every one that I had no surreptitious design in using the cuts. In the mule litters and cacolets now issued in the French army there are improvements providing for making the sections of the litter rigid, so that it can be used temporarily as a hand-stretcher, for reduction in weight, and for greater compactness in packing.[1] The mule chairs and litters now issued by the British Royal Carriage Department are lighter and more convenient than those used in the Crimea. I take the liberty of copying Surgeon General Longmore's drawings of the cacolet (FIG. 448) and litter (FIG. 449) now employed in the British service.[2] The only reference I find of the actual employment in battle, during the late war in this country, of horse litters or cacolets, is made by Professor F. H. Hamilton. He mentions that, at the battle of Fair Oaks, May 31, 1862, when he was Medical Director of the Fourth Army Corps, eight pack-saddles, pro-

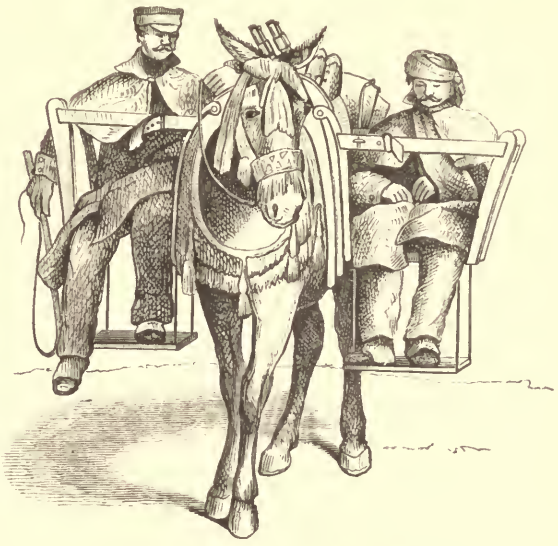

FIG. 447.—British Crimean cacolet. [After WEIR.]

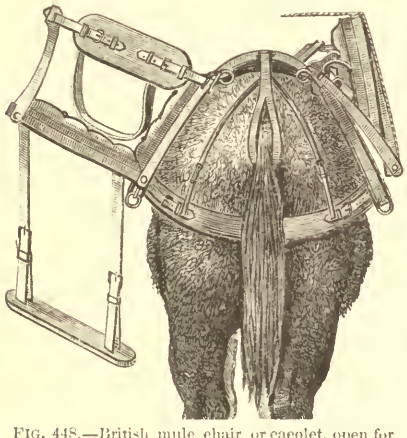

FIG. 448.—British mule chair or cacolet, open for use and packed for traveling. [After LONGMORE.]

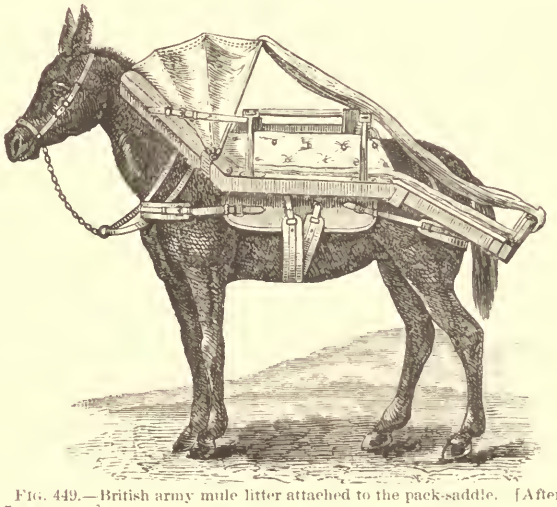

FIG. 449.—British army mule litter attached to the pack-saddle. [After LONGMORE.]

[1] M. BOUDIN states (*Système d'ambulances des armées Française et Anglaise*, 1855, p. 35) that the cacolet weighed something over 19 kilogrammes the pair. The pair in the Army Medical Museum weighs 40 pounds. Including the pack-saddle, Professor LONGMORE says a pair weighed in the Crimea was found to be 89 pounds and 12 ounces.

[2] The weight of a pair of English litters used in the Crimea was 138 pounds 12 ounces without the pack-saddle. The present pattern weighs 84 pounds without bedding or pack-saddle. With palliasses and pack-saddle the weight is 167 pounds.

vided with a litter on one side and a cacolet on the other, were provided as a part of the ambulance outfit of that corps, and were used only on the first day of the battle, proving utterly unserviceable.[1] Notes are found in the War Department of the transmission, August 26, 1861, of twelve of the mule litters and cacolets made by Tiffany & Co., to the army in the Shenandoah Valley, commanded by General Banks. A supply of litters and cacolets was provided for the advance of the Army of the Potomac from Yorktown toward Richmond, in May, 1862. There were forty, at least, in store at White House,[2] but there were no trained animals to bear them. Moreover, the subordinate quartermasters and medical officers appear generally to have regarded the experiment with little favor. Medical Director Tripler, who, in 1859, in a report on the needs of the ambulance service, had urged the importance of supplying horse litters to troops serving in regions impracticable for wheeled carriages, made several efforts to secure suitable equipment and proper animals[3] for this purpose, but without much success. His successor also, Medical Director Letterman, entertained similar views, in correspondence with the opinions of European authorities; and persevering, though ill-arranged, efforts were made to give the system a fair trial. In July, 1862, the Surgeon General requested the Quartermaster's Department to provide three hundred litters, and this number was purchased of Mr. G. Kohler.[4] Prior to the battle of Antietam Medical Director Letterman asked for a supply of mules equipped with cacolets and litters.[5] The Quartermaster's Department had an ample supply of the French patterns, which were beyond all question the best that had been devised at that time. But there were no trained animals to bear them, and few, if any, available skilled packers. September 1, 1862, the Surgeon General requested that a hundred mule litters should be sent to Medical Inspector R. H. Coolidge. A few weeks after the battle of Antietam a hundred and fifty mules were sent to the Army of the Potomac for ambulance service, but they were so unruly that it was thought unwise to pack them with their equipment, and the litters and cacolets were sent along in wagons, and, as far as can be learned, never found their way to the backs of the mules.[6] Little could be anticipated from such essays. In November, 1862, the Sur-

[1] HAMILTON (F. H.) (*A Treatise on Military Surgery and Hygiene*, 1865, p. 162): "Just before the battle of Fair Oaks, eight were sent to us for the use of the 4th corps. They were only employed, however, on the first day of the battle. The horses were found to be impatient and restless under them, and six of the eight were soon broken and rendered unfit for use. Mules are better than horses for this purpose; they are not so high, and are less restive under the pressure of heavy weights upon their backs; but even mules require to be trained especially to this kind of service before they can be rendered useful or safe."

[2] From a telegraphic order of May 27, 1862, recorded on the files of the War Department, and addressed from the Headquarters of the Army of the Potomac, by Lieutenant Colonel J. A. HARDIE, to Colonel S. VAN VLIET, Quartermaster, at White House on the Pamunkey, it appears that a certain number of cacolets were at that depot prior to the battle of Fair Oaks. The dispatch reads: "The Commanding General directs that you furnish the forty cacolets at the White House, belonging to the Medical Department, with horses, and report to the Medical Director here the moment they are ready." Doubtless the eight cacolets sent to the Fourth Corps were supplied from this source.

[3] March 13, 1862, on receiving the papers regarding Mr. KOHLER'S request for an examination of his litters and cacolets, Medical Director TRIPLER makes the indorsement that: "there are sufficient horse litters for this army in the possession of the Quartermaster's Department. All we want now is horses or mules properly trained to carry them. On April 25, 1862, Dr. TRIPLER stated that there were some 200 or more cacolets furnished by the Quartermaster's Department, and that he made every effort to have horses trained to carry them with their loads; that orders to that effect were issued by General McClellan, but were not executed.

[4] June 17, 1862, Colonel RUCKER advises the Quartermaster General that he has advertised for proposals for mule litters, and that the only proposal received is from Mr. G. KOHLER, and that the litter he proposes to furnish seems to be very high priced: "It is intricate and cumbersome in construction, and, in my opinion, inferior to those now in Captain DANA'S store-house" [the French cacolet and litière]. July 26, 1862, Surgeon General HAMMOND states, in reply to a letter from the Quartermaster General concurring in Colonel Rucker's opinion: . . . "The litter presented by Mr. KOHLER has been examined by myself and a board of officers, who agree that it possesses sufficient merit to entitle it to trial in the field. I therefore request that *three hundred* of the mule litters presented by Mr. KOHLER be purchased for the use of the army." Quartermaster General MEIGS replies, July 29, 1862, that . . . "inasmuch as the Surgeon General adopts and requests that these litters be constructed, though in the opinion of the Quartermaster's Department they are not as good as those already on hand, they will be contracted for under the proposal of Mr. KOHLER. The price bid is understood, as in other cases, to include the whole set, namely: head-stall, harness, saddle, and two litters for each mule." As early as December 9, 1861, this pattern of mule litter had been reported on by a board convened by General MCCLELLAN, consisting of Colonel D. H. RUCKER, Surgeon C. H. LAUB, and Surgeon J. R. SMITH, it is presumed unfavorably, as further action was not had at the time.

[5] The records of the Property Division of the Surgeon General's Office show that during the period from 1861 to 1865, nine hundred and eighteen horse or mule litters were purchased and distributed by the Medical Department. Of these, 417 were manufactured in the depot at New York, and the rest were purchased from Tiffany & Co., of New York, Wyeth & Brother, of Philadelphia, A. F. Coldeway, Louisville, Ky., and Suire & Eckstein, of Cincinnati, Ohio.

[6] In October, 1862, the Surgeon General again made requisition on the Quartermaster's Department for one hundred and fifty mules provided with mule litters, to be sent to Dr. JONATHAN LETTERMAN, Medical Director of the Army of the Potomac. In reference to delay in compliance with this

geon General made another requisition for a hundred and fifty mules with drivers, with a view of having them drilled with cacolets in the field by Dr. Slade Davis; but this, like previous experiments in this direction, proved abortive; and the ambulance material for transport by pack-animals, accumulated at no inconsiderable cost, was never really tested in the field.[1] There seems to have been a widespread distrust of the system on the part of officers of the Quartermaster's and the Medical Departments.

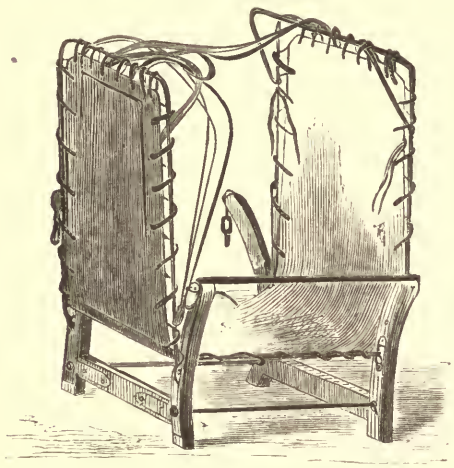

FIG. 450.—French litière folded. [After LEGOUEST.]

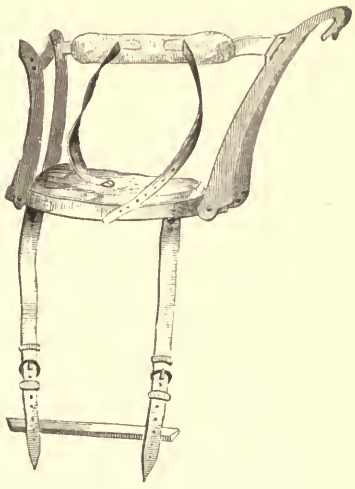

FIG. 451.—French cacolet unfolded. [After LEGOUEST.]

"In a letter of March 20, 1863, Surgeon George Suckley, U. S. V., Medical Director of the Eleventh Corps, wrote from the Army of the Potomac, near Fredericksburg, to Surgeon J. H. Brinton, U. S. V., at Washington: 'There are no cacolets in this corps, and I want none. Three hundred and fifty pounds weight is too much for a mule's back over rough ground, encumbered by bushes, stones, logs, and ditches. Among trees, cacolets will not answer at all; although used in European services and in Algeria, they have there been employed under some favorable circumstances, either on plains or on open rolling country. Here they would prove, I sincerely believe, only a troublesome and barbarous encumbrance, cruel alike to the wounded and the pack-animals.'"

AMBULANCE CORPS.

The necessity for a drilled and instructed corps for the transportation of wounded from the field is apparent to every one who will consider the subject. The importance of having the wounded rapidly removed from the scene of strife must be conceded, not only on the score of humanity, but also as a military necessity. Without a detachment whose service

requisition Captain J. J. DANA, A. Q. M., reported October 17, 1862, as follows: "The order was given by me October 3d, immediately on its receipt, for one hundred and fifty mules and litters to be made ready for service. At that time we had no mules sufficiently well broken for the purpose. I directed fifty of the best to be taken from the ambulance train, the litters to be fitted upon them, and the mules drilled daily until they were fit to go into the field. On the 9th of October fifty mules, with litters upon them, were started for Dr. LETTERMAN. Much difficulty was experienced in getting the mules forward, as they were, many of them, inclined to lie down, and were otherwise unruly. Among a lot of mules received on the 10th instant we found one hundred which were, to some extent, suitable for the purpose, and were sent forward on the 11th instant, the litters being sent by wagons in order to expedite the matter." October 3, 1862, Quartermaster General MEIGS, in transmitting this report to Surgeon General HAMMOND, stated: "I desire respectfully to call your attention to the fact mentioned in the report: that there are a large number of cacolets now in the possession of the Government which appear to have been overlooked by the officers of your Department, and to suggest the expediency of directing their availing themselves of them as occasion may arise. General MCCLELLAN issued orders, a year ago, for drill and practice of ambulance men, including, as I understand, the use of the mule litters, of which, of French and American manufacture, there were then a considerable number provided by the Quartermaster's Department. Those lately purchased from Mr. KOHLER, on the requisition of the Surgeon General, cost $21,060 and are still in store."

[1] "From the papers laid before the Quartermaster General to-day, there appears an expenditure for purchase of cacolets and litters in 1861 and 1862 for the army, partly upon requisitions from the Surgeon General, partly from orders originating in this office, of over $20,000. To this, if the cost of animals and use of men, of forage, etc., supplied by this Department for the experiment of introducing these litters and cacolets, it would be found that not less than $100,000, and probably more, has been expended in an experiment which was, so far as information in this office goes, entirely unsuccessful. There never was, to the knowledge of the Quartermaster General, a requisition from any military commander. All the requisitions came from the Surgeon General's Office. It is not known to this office that these mule litters ever were used in service, and the Quartermaster General believes that no wounded man was ever placed upon one of them. While the wheeled ambulances and hand litters provided for the hospital equipments were in constant and useful use, the litters burdened the trains, and the mules were, by the ordinary accidents of service, taken for the ambulances and wagons. He believes that no better cacolets or mule litter will be constructed than the French cacolet and litter, ordered at the beginning of the rebellion; and these, which though in his judgment inferior, were, at a later period, bought at the urgent requisition of the then Surgeon General. He is, therefore, of opinion that any further expenditure by this Department in this line of experiment will be a waste of public money, and he will not, therefore, unless under order of higher authority, expend money or make reports upon any models thus far submitted to him.—*Mem. of* QUARTERMASTER GENERAL, December 23, 1863.

it is to attend to this duty, the natural impulse of sympathy will draw men from the ranks to assist their fallen comrades, while the pretext is a temptation to the faint-hearted to shirk the perils of their position. Moreover, the courage of troops under fire would be sustained if they were assured that reliable men would be ready to bear them rapidly from the vicissitudes of a conflict and to tender them early assistance.

No organized ambulance corps[1] existed in the army at the beginning of the war, but the necessity of such an organization under the control of the Medical Department was

[1] Propositions were made by citizens early in the war to aid in the establishment of an ambulance corps. In May, 1861, Dr. J. O. BRONSON, of New York, urged upon General Winfield Scott the formation of an organization to consist of a surgeon-in-chief, with aids, nurses, and an efficient body of men to attend upon the ambulance and litters. The letter was referred by General Scott to the Surgeon General, but no further action seems to have been taken. On September 19, 1861, the Surgeon General of Pennsylvania, Dr. H. H. SMITH, wrote to Surg. C. S. TRIPLER, U. S. A., Medical Director of the Army of the Potomac: "I shall have at Camp Curtin, near Harrisburg, in a few days, fifteen of your ambulances, thirty of those of Coolidge, and fifteen transport carts, with harness complete, ready to send to the Pennsylvania Reserve Corps. I should like to enlist, if authorized, and drill for one week at this camp, teamsters as drivers, with non-commissioned and commissioned officers, at the same pay as similar grades in the Army. The corps would consist as follows: One driver to each carriage—60 drivers; one corporal, mounted, to fifteen carriages—4 corporals; one sergeant, mounted, to a division (20 carriages)—3 sergeants; two second lieutenants—2 officers; 67 men. This company would have its motions in transportation directed by the lieutenants, who would be commanded by the surgeon of brigade, etc.; the officers and drivers dismounting to lift wounded men, and, whilst carriages went to a hospital and back, could ride round and give temporary assistance with tourniquets, canteens, etc. This may suffice to show my general ideas, which can readily be made to conform to Army Regulations when I am authorized to do so. Not knowing who to apply to, I place the matter in your hands, asking a prompt reply, that no time may be lost, especially if wanted. Such a corps would serve to drill and form others. When not acting with ambulances the corps could attend to general police of sinks, stables, water, fuel, etc., aided by guard-house prisoners, and relieving guard of such duties, or act as extra nurses, cooks, wardmasters, etc., of regimental hospitals. Many volunteer regiments are deficient in these men—those having them could organize an ambulance corps readily." Surgeon TRIPLER forwarded this letter to the honorable Secretary of War with the following endorsement: "The plan suggested by Dr. SMITH, if authorized to be carried out, would meet a pressing want—that of having properly instructed men to handle the wounded. The only difficulty in the way is that medical officers are not *now* authorized to command lieutenants. The necessity for that authority, however, becoming daily more apparent, it is hoped it may be granted, at the next session of Congress, to the same extent as in the other staff departments. The whole plan of Dr. SMITH is, therefore, earnestly recommended to the favorable consideration of the honorable Secretary of War." No action was had on this recommendation. In the early spring of 1862 a plan was submitted to the Secretary of War by Mr. CHARLES PFIRSCHING: "To every division of the army a company shall be attached which will follow it immediately into action on the day of battle for the purpose of taking up all its wounded and carrying them back to the ambulances, or to the points where the regimental surgeons have taken position. Each man of this company should be armed and equipped in the following manner: Two navy revolvers, carried in the cartridge-box belt; a hatchet, carried on the left side of the cartridge-box belt; a cartridge-box on a leather belt; a knapsack half filled with his own things, while the other half is appropriated to a stock of bandages, linen, lint, etc., as they may be necessary for a bandage to prevent the death of the wounded before he obtains the assistance of the surgeon. Besides some prepared sticking plasters, etc., and some bottles with stimulating essences to recall the spirits of the wounded, or to enable him to bear the pains of his wound and of the transportation, a large canteen with water, to which some vinegar or pure brandy may be added for the use of the wounded; a tin tumbler with it; a small canteen for the man's own use; a small box on the cartridge-box belt, with lint, bandages, a small bottle of vinegar for immediate use, so that he has not to take off his knapsack; the half of a litter of my own invention. Two men of this company always keep together, and by means of their two halves they form a litter on which they carry the wounded from the battle-field to the ambulances, or to the places where the regimental surgeons have established themselves. Every man has a broad bandoleer of black leather from the left shoulder to the right hip, and one from the right shoulder to the left hip, with a sling to each to put the ends of the litter through, so that the weight of the load rests on it, and that the men may have one or both hands free if they should be obliged to make use of their weapons. Each man should have a small whistle to give signals to other members of his company. Each company should have one first and one second lieutenant, and as many non-commissioned officers as there are regiments in the division. If brigades or regiments should be detached from the division, a corresponding number of platoons would be detached from the ambulance companies with them. All ambulance companies of the army should be under the command of a colonel. The men would be instructed in a particular drill for their particular duties on the battle-field. The two or four wheeled ambulances would then be stationed on a convenient place in the rear of the different regiments, and with them might be stationed the regimental surgeons to give the wounded the first regular assistance before they are sent farther back. By this arrangement not only a great deal of pain and suffering might be spared to the wounded, but a great many lives might be saved also. In an economical point of view a saving would also be made, for the ambulances would last a good deal longer than at present. All the confusion with the wounded at present on the battle-fields would be avoided; the ranks would not be broken by men who want to assist their wounded comrades, or who use this excuse to cover their cowardice. The men of the ambulance companies would be detached from the different regiments of every division, say one man from every company. I am willing to undertake the formation and instruction of these companies, and to take the command of them. (Signed) CHARLES PFIRSCHING." The Secretary of War directed, on March 3, 1862, Surgeon-General C. A. FINLEY to examine, or cause to be examined, this plan, and report. Surgeon General FINLEY sent the paper to Surgeon CHARLES S. TRIPLER, U. S. A., Medical Director of the Army of the Potomac, requesting his views with regard to its adaptability to the service and with regard to the question whether the proper organization of the bands in the field would not obviate the necessity for the proposed organization. The report of Surgeon TRIPLER is appended: "Headquarters Army of the Potomac, Medical Director's Office, Washington, March 6, 1862. Sir: I have the honor to report that, in obedience to your instructions, I have examined the plan of organization of an ambulance corps submitted by CHARLES PFIRSCHING. However desirable a regularly organized ambulance corps may be for an army, it is too late now to raise, drill, and equip so elaborate an establishment as this for our service. There is nothing new in this plan, nothing that has not been thought of and well weighed years ago in connection with our own organization, unless it be the arsenal of pistols and hatchets with which the men are to be loaded. As we have no ambulance corps proper, an attempt has been made to instruct a certain number of men in each regiment in the duties appertaining to such a corps. An order providing for the drilling of ten men and the band of each regiment to the ambulance service was issued from these headquarters on the 3d of October, 1861. This has been generally faithfully done, and we now have a tolerably well instructed body of men for this duty. Instructions for the distribution and employment of these men during an action have been prepared by me and even submitted to General Williams, Adjutant General of the Army of the Potomac, for the action of General McClellan, some ten days ago. I hope they will soon be printed and circulated. When that is done all necessary and practicable arrangements for the transportation of our wounded will have been made. I am, therefore, of opinion that the plan of Mr. PFIRSCHING is neither needed nor available for our service at the present time. Very respectfully, your obedient servant. (Signed) CHAS. S. TRIPLER, Surgeon and Medical Director, Army of the Potomac." The report of Surgeon TRIPLER was returned, on March 7th, to the Secretary of War by the Surgeon General, who fully endorsed the views of Surgeon TRIPLER.

early recognized by the medical officers, and already in April, 1862, Medical Director Tripler, of the Army of the Potomac, called attention to the absolute necessity of having an experienced quartermaster and assistant commissary of subsistence attached to the command of the Chief Medical Officer of an army in the field: "I find it impossible to secure either transportation or subsistence for the men thrown upon my hands without tedious delays and much unnecessary suffering. Time, which is so valuable to me now, is taken up and wasted in endeavors, too often unsuccessful, to get together ambulances and wagons[1] to have these trains properly and economically conducted, to have boats prepared and in position, to procure buildings for hospitals, to get subsistence for the sick and wounded, and, in short, doing the duty assigned to quartermasters and subsistence officers. It seems to me that to bring this evil to the notice of the Secretary of War will be sufficient to cause its instant remedy; at all events, I protest beforehand against the Medical Department being held responsible for evils they have no possible means of obviating. My experience in this campaign has taught me that without an executive officer of these two important departments under my command, more time is lost in negotiating through second and third parties, with an even chance of not getting at all what is wanted, and a certainty of not getting it in time, than would be required in procuring what is necessary and having it in the right place if these officers were placed at my disposal."

On August 21, 1862, Surgeon General W. A. Hammond, U. S. Army, in a letter to the Secretary of War, urged the necessity for such a corps:

"SURGEON GENERAL'S OFFICE,
"WASHINGTON, *August* 21, 1862.

"Honorable EDWIN M. STANTON,
Secretary of War.

"SIR: In accordance with your verbal permission, I have the honor to submit to you the inclosed project for an Hospital Corps, and to ask your favorable consideration for the same. The plan is merely submitted as a basis on which the corps can be organized; much will remain to be done by regulations, and I propose, should you approve the inclosed outline, to ask for a board of medical officers to perfect the organization. I have not considered it necessary to enter into details; the first thing essential is to obtain your sanction to the organization of such a corps. The need for it is most urgent. In no battle yet have the wounded been properly looked after; men under pretence of carrying them off the field leave the ranks and seldom return to their proper duties. The adoption of this plan would do away with the necessity of taking men from the line of the army to perform the duties of nurses, cooks, and attendants, and thus return sixteen thousand men to duty in the ranks. In view of these facts, and many others which could be adduced, I respectfully ask your approval of the inclosed project.

'I am, sir, very respectfully,
"Your obedient servant,
(Signed) "WILLIAM A. HAMMOND,
"*Surgeon General.*"

To this the following answer was received:

"WAR DEPARTMENT,
"WASHINGTON CITY, D. C., *August* 29, 1862.

"SIR: The Secretary of War directs me to acknowledge the receipt of your communication of the 21st instant, submitting a project for a Hospital Corps, and to inform you that the subject was referred to the General-in-Chief, whose views, adverse to the project, are expressed in the following words: 'Our army trains are already much too large and very seriously impede the movements of our troops in the field. The enemy have great advantages over us in this respect. To

[1] It will be shown hereafter that the importance of having the ambulance wagons under the control of the Medical Department had, before the war, been pointed out by a board of medical officers consisting of Surgeons R. S. SATTERLEE, C. H. LAUB, and Assistant Surgeon C. H. CRANE, U. S. A., who, in March, 1858, had been appointed a board to examine and report upon the Moses' ambulance wagon.

organize such a medical force as is here proposed would, besides involving enormous expenses, greatly increase this evil. Moreover, the presence of non-combatants on, or near the field of battle, is always detrimental, as most panics and stampedes originate with them. Medical soldiers would not obviate the necessity of sending fighting soldiers from their ranks with their wounded, for the former would seldom be near enough to the enemy to perform that duty. The soldier can be very much relieved by hiring cooks, nurses, and attendants in hospitals, whenever the circumstances will permit; but I can see no advantage in having them enlisted for that special purpose. All persons so employed are, by law, subject to Army Regulations. I regard this project as one calculated to increase the expenses and immobility of our army by adding to it a large corps of non-combatants, without any corresponding advantages. I therefore report against its adoption.'

"Very respectfully, your obedient servant,

"SURGEON GENERAL, (Signed) "P. H. WATSON,
Washington, D. C." "*Assistant Secretary of War.*

A second appeal was made to the Secretary of War on September 7, 1862:

"SURGEON GENERAL'S OFFICE,
"WASHINGTON CITY, D. C., *September* 7, 1862.

"SIR: I have the honor to ask your attention to the frightful state of disorder existing in the arrangements for removing the wounded from the field of battle. The scarcity of ambulances, the want of organization, the drunkenness and incompetency of the drivers, the total absence of ambulance attendants, are now working their legitimate results, results which I feel I have no right to keep from the knowledge of the Department. The whole system should be under the charge of the Medical Department; an ambulance corps should be organized and set in instant operation. I have already laid before you a plan for such an organization, which I think covers the whole ground, but which I am sorry to find does not meet with the approval of the General-in-Chief. I am not wedded to it. I only ask that *some* system may be adopted by which the removal of the sick from the field of battle may be speedily accomplished, and the suffering to which they are now subjected be, in future, as far as possible avoided. Up to this date six hundred wounded still remain on the battle-field in consequence of an insufficiency of ambulances and a want of a proper system for regulating their removal in the Army of Virginia. Many have died of starvation, many more will die in consequence of exhaustion, and all have endured torments which might have been avoided. I ask, sir, that you will give me your aid in this matter; that you will interpose to prevent a recurrence of such consequences as have followed the recent battle, consequences which will inevitably ensue on the next important engagement, if something is not done to obviate them.

"I am, sir, very respectfully,
"Your obedient servant,

"Hon. E. M. STANTON, (Signed) "WILLIAM A. HAMMOND,
Secretary of War." "*Surgeon General, U. S. A.*

This also was referred to the General-in-Chief and returned endorsed as follows:

"HEADQUARTERS OF THE ARMY,
"WASHINGTON, *September* 15, 1862.

"I am informed by the Quartermaster General that every effort is being made to supply a large number of ambulances. It is proper to remark, however, that the enemy have provided for their wounded on every battle-field with not one-half the ambulances and other facilities provided for our armies. I do not perceive how the drunkenness and incompetency of drivers are likely to be prevented any more by putting the ambulances exclusively under the direction of the Medical Department. It is the duty of all officers to furnish fatigue parties, properly officered, on the requisition of medical officers, for the care and removal of the wounded, and it is the duty of all medical officers to make such requisitions, and if not filled, to report the neglect. No such neglect has been reported by medical officers on the recent battle-fields. My objection to the proposed organization of a separate non-combatant corps to be attached to the Medical Department were set forth in my endorsement upon a former letter of the Surgeon General.

(Signed) "H. W. HALLECK,
"*General-in-Chief.*"

Owing to the opposition of the General-in-Chief, no further steps were taken in this direction at this time. In the meantime the medical officers in the field had been compelled to devise the best means they could for the immediate care of the wounded after battles. At the suggestion of Medical Director Tripler, the following order was issued in the Army of the Potomac on October 3, 1861:

"HEADQUARTERS ARMY OF THE POTOMAC,
"WASHINGTON, *October* 3, 1861.

"GENERAL ORDERS No. 20.

* * * * * * * *

"VI.—The hospital attendants, to the number of 10 men to a regiment, and the regimental bands, will be assembled under the supervision of the brigade surgeons, and will be drilled one hour each day, except Sunday, by the regimental medical officers, in setting up and dismantling the hand-stretchers, litters, and ambulances; in handling men carefully; placing them upon the litters and ambulance beds; putting them into the ambulances, taking them out, etc.; carrying men upon the hand-stretchers (observing that the leading bearer steps off with the *left* foot and the rear bearer with the *right*); in short, in everything that can render this service effective and the most comfortable for the wounded who are to be transported.

* * * * * * * *

"BY COMMAND OF MAJOR GENERAL MCCLELLAN:
(Signed) "S. WILLIAMS,
"*Assistant Adjutant General.*"

Similar plans were adopted in other armies, but the first and most complete ambulance system[1] was that established in August, 1862, at the instance of Surgeon Jonathan Letterman, U. S. A., Medical Director of the Army of the Potomac. The plan is clearly set forth in the accompanying order:

"HEADQUARTERS ARMY OF THE POTOMAC,
"CAMP NEAR HARRISON'S LANDING, VA., *August* 2, 1862.

"GENERAL ORDERS No. 147.

"The following regulations for the organization of the Ambulance Corps and the management of ambulance trains are published for the information and government of all concerned. Commanders of Army Corps will see that they are carried into effect without delay:

"1. The Ambulance Corps will be organized on the basis of a captain to each Army Corps as

[1] A crude draft of a plan for the establishment of an ambulance corps had, on July 15, 1862, been submitted to the Surgeon General by Surgeon B. A. VANDERKIEFT, U. S. V., as follows: "Each division shall be provided with a special corps under the name of 'Division Ambulance Corps.' This corps will be under the immediate orders of the Division Medical Director. This corps will be composed of one hundred private soldiers and four non-commissioned officers, under the orders of a medical officer with the rank of surgeon, who will be aided in his duties by an assistant surgeon; both being detailed from respective regiments, and being exempt from all duties save those connected with the above mentioned corps. The non-commissioned officers attached to this corps will have the rank and pay of hospital stewards, and the privates will receive the additional pay of hospital attendants. Among the privates four will be detailed to act as cooks. One blacksmith shall be attached to the corps. The four non-commissioned officers to be mounted. The men composing the Division Ambulance Corps will be selected from the different regiments forming the division; and preference will be given to hospital attendants recommended by their respective surgeons as being competent, intelligent, and of unimpaired physique. As means of transportation there will be required: 12 four-wheeled four-horse ambulances; 12 two-wheeled one-horse ambulances for transportation of sick and wounded; 1 four-wheeled two-horse ambulance, containing the medical stores on hand and serving as an ambulating surgery; 2 four-wheeled four-horse transport wagons, for transporting medical stores and provisions. The corps, having no permanent place of settlement, should always be provided with a few days' rations for attendants and patients. Rations and forage should be drawn by the medical officer in charge from the division commissary. Every man belonging to this corps shall be instructed, if possible, four hours each day in the following exercises: Transportation of sick and wounded; removing sick and wounded in ambulances from the field of battle; attendance of the wounded on the field before the arrival of the surgeon, such as applying tourniquets and bandages to prevent fatal bleeding, etc. The building of provisional hospitals *(abris)*, where no other means offer, and the construction of *impromptu* bunks and litters will also form part of the instruction of attendants, to make them more thoroughly efficient for their position. Each man shall be provided with a bag containing a tourniquet, lint, linen, bandages, and a few hæmostatic and stimulant medicines, the use of each having been explained. During and after a battle or engagement, the surgeon in charge shall always superintend the transportation of the wounded, not only by his own corps, but even by the different regimental ambulance corps. In cases where it may be absolutely required, operations on the field should even be performed by the surgeon in charge or his assistant surgeon, but only in the absence of the proper regimental surgeon, such privilege belonging properly to him. After an engagement the division ambulances shall be used for transporting the sick and wounded to the central hospitals; and when the division is only moving they shall assist the different regiments in the transportation of the sick, thus preventing the numerous stragglers arising from insufficient means of regimental transportation. When the corps has attained a certain degree of proficiency, the men composing it may be gradually returned to the departments from which they have been taken, and new ones detailed who shall be instructed in the same exercises. The division ambulance corps is thus not only intended for the transportation of sick and wounded, but to be a school of instruction to form well-disciplined hospital attendants."

the Commandant of the Ambulance Corps, a 1st lieutenant for a Division, 2d lieutenant for a brigade, and a sergeant for each regiment.

"2. The allowance of ambulances and transport carts will be: One transport cart, one 4-horse and two 2-horse ambulances for a regiment; one 2-horse ambulance for each battery of artillery, and two 2-horse ambulances for the Headquarters of each Army Corps. Each ambulance will be provided with two stretchers.

"3. The privates of the Ambulance Corps will consist of two men and a driver to each ambulance, and one driver to each transport cart.

"4. The captain is the commander of all the ambulances and transport carts in the Army Corps, under the direction of the Medical Director. He will pay special attention to the condition of the ambulances, horses, harness, etc., requiring daily inspections to be made by the commanders of Division ambulances, and reports thereof to be made to him by these officers. He will make a personal inspection once a week of all the ambulances, transport carts, horses, harness, etc., whether they have been used for any other purpose than the transportation of the sick or wounded, and medical supplies; reports of which will be transmitted through the Medical Director of the Army Corps to the Medical Director of the Army every Sunday morning. He will institute a drill in his corps, instructing his men in the most easy and expeditious method of putting men in and taking them out of the ambulances, taking men from the ground and placing and carrying them on stretchers, observing that the front man steps off with the left foot and the rear man with the right, etc. He will be especially careful that the ambulances and transport carts are at all times in order, provided with attendants, drivers, horses, etc., and the keg daily rinsed and filled with fresh water, that he may be able to move at any moment. Previous to and in time of action he will receive from the Medical Director of the Army Corps his orders for the distribution of the ambulances and the points to which he will carry the wounded, using the light two horse-ambulances for bringing men from the field, and the four-horse ones for carrying those already attended to farther to the rear, if the Medical Director considers it necessary. He will give his personal attention to the removal of the sick and wounded from the field and to and from the hospitals, going from point to point to ascertain what may be wanted, and to see that his subordinates (for whose conduct he will be responsible) attend to their duties in taking care of the wounded, treating them with gentleness and care, and removing them as quickly as possible to the places pointed out; and that the ambulances reach their destination. He will make a full and detailed report after every action and march of the operations of the Ambulance Corps.

"5. The 1st lieutenant assigned to the Ambulance Corps of a Divison will have complete control, under the Commander of the whole Corps and the Medical Director, of all the ambulances, transport carts, ambulance horses, etc., in the Division. He will be the Acting Assistant Quartermaster for the Division Ambulance Corps, and will receipt and be responsible for the property belonging to it, and be held responsible for any deficiencies in ambulances, transport carts, horses, harness, etc., pertaining to the Ambulance Corps of the Division. He will have a travelling cavalry forge, a blacksmith, and a saddler, who will be under his orders, to enable him to keep his train in order. He will receive a daily inspection report of all the ambulances, horses, etc., under his charge from the officer in charge of Brigade Ambulance Corps, will see that the subordinates attend strictly to their duties at all times, and will inspect the corps under his charge once a week; a report of which inspection he will transmit to the Commander of the Ambulance Corps.

"6. The 2d lieutenant in command of the ambulances of a brigade will be under the immediate orders of the commander of the Ambulance Corps for the Division, and have superintendence of the Ambulance Corps for the brigade.

"7. The sergeant in charge of the Ambulance Corps for a regiment will conduct the drills, inspections, etc., under the orders of the Commander of the Brigade Ambulance Corps, and will be particular in enforcing rigidly all orders he may receive from his superior officers. The officers and non-commissioned officers of this corps will be mounted.

"8. The detail for this corps will be made with care by Commanders of Army Corps, and no officer or man will be selected for this duty except those known to be active and efficient; and no man will be relieved except by orders from these Headquarters. Should any officer or man detailed for this duty be found not fitted for it, representations of the fact will be made by the Medical Director of the Army Corps to the Medical Director of this Army.

"9. Two medical officers from the reserve corps of surgeons of each Division, and a hospital steward who will be with the medicine wagon, will be detailed by the Medical Director of the Army Corps to accompany the ambulance train when on the march, the train of each Division being kept together, and will see that the sick and wounded are properly attended to. A medicine wagon will accompany each train.

"10. The officers connected with the corps must be with the trains on the march, observing that no one rides in the ambulances without the authority of the medical officers, except in urgent cases; but men must not be allowed to suffer, and the officers will, when the medical officers cannot be found, use a sound discretion in this matter, and be especially careful that the men and drivers are in their proper places. The place for the ambulances is in front of all the wagon trains.

"11. When in camp the ambulances, transport carts, and Ambulance Corps will be parked with the brigade, under the supervision of the commander of the corps for the brigade. They will be used on the requisition of the regimental medical officers, transmitted to the Commander of the Brigade Ambulance Corps, for transporting the sick to various points and procuring medical supplies, and *for nothing else.* The non-commissioned officer in charge will always accompany the ambulances or transport carts when on this or any other duty, and he will be held responsible that they are used for none other than their legitimate purposes. Should any officer infringe upon this order regarding the uses of ambulances, etc., he will be reported by the officer or non-commissioned officer in charge to the commander of the train, all the particulars being given.

"12. The officer in charge of a train will at once remove anything not legitimate, and if there be not room for it in the baggage wagons of the regiment, will leave it on the road. Any attempt by a superior officer to prevent him from doing his duty in this or any other instance he will promptly report to the Medical Director of the Army Corps, who will lay the matter before the commander of that corps. The latter will, at the earliest possible moment, place the officer offending in arrest for trial for disobedience of orders.

"13. Good, serviceable horses will be used for the ambulances and transport carts, and will not be taken for any other purpose, except by orders from these Headquarters.

"14. The uniform of this corps is: For privates, a green band two inches broad around the cap, a green half chevron two inches broad on each arm above the elbow, and to be armed with revolvers. Non-commissioned officers to wear the same band around the cap as a private, chevrons two inches broad, and green, with the point toward the shoulder, on each arm above the elbow.

"15. No person will be allowed to carry from the field any wounded or sick, except this corps.

"16. The Commanders of the Ambulance Corps, on being detailed, will report without delay to the Medical Director at these Headquarters for instructions. All Division, Brigade, or Regimental Quartermasters having any ambulances, transport carts, ambulance horses or harness, etc., in their possession, will turn them in at once to the Commander of the Division Ambulance Corps.

"By command of Major General McClellan:

(Signed) "S. WILLIAMS,
"*Assistant Adjutant-General.*"

The advantages accruing from this organization became speedily manifest. At the battle of Antietam, in September, 1862, by the active and energetic exertions of the members of this corps the disabled of the right wing of the army (there was no ambulance system on the left) were rapidly conveyed from the scene of conflict to the hospitals in the rear. The train of ambulances plied incessantly between the battle-ground and the field hospital. During the night of the battle all of our wounded in the widely extended field were removed to shelter and received the necessary surgical attention. Different members of the corps behaved with the utmost gallantry, passing freely under fire in their search of the fallen, and advancing at times to the extreme verge of the enemy's pickets. All of our wounded having thus been collected at the temporary depots, such as were deemed best able to undergo further transportation were carefully selected. These, during the following two or three days, were then conveyed by the ambulance train to Frederick City, Md.,—the nearest point of railway connections. At the first battle of Fredericksburg the results

of the persevering endeavors of the Ambulance Corps were not less happy. During the night following the battle all of the wounded remaining on the ground not absolutely in the hands of the enemy were safely conveyed to the city of Fredericksburg and its neighborhood. When it subsequently became necessary to evacuate the city of Fredericksburg for military reasons, the wounded were again placed upon the train and safely reached the opposite bank of the river. These fortunate results were, however, obtained at the expense of the Ambulance Corps, which experienced a loss of one officer and several privates killed, besides others who were captured during their humane efforts to remove their fallen countrymen.

In the Army of the Tennessee, with the exception of General Sherman's Corps, no system for the formation of an ambulance train, for confining ambulances to their proper use, or for the ready removal of wounded had existed prior to March, 1863, when Medical Inspector E. P. Vollum, U. S. A., urged upon General Grant the necessity of establishing an ambulance corps. The proposition was cheerfully entertained, and on March 30, 1863, the following order was issued from the Headquarters of the Department of the Tennessee:

"HEADQUARTERS DEPARTMENT OF THE TENNESSEE,
"YOUNG'S POINT, LOUISIANA, *March* 30, 1863.

"GENERAL ORDERS No. 22.

"Army Corps Commanders will at once enforce the following regulations:

"1. All ambulances with the Army in the field will be turned in to Division Quartermasters, each Division retaining all the ambulances it now has.

"2. Division ambulance trains will be formed in charge of one commissioned officer for each Division, one non-commissioned officer for each brigade, and one driver and two enlisted men for each ambulance, to be detailed for that purpose, who will be subject to the direction of the Chief Surgeon of the Division.

"3. The officers in charge of Division ambulance trains will have direct military control over all the non-commissioned officers and privates of their respective trains, and will see that the ambulances are only used for conveying sick or wounded, carrying provisions for hospitals when necessary, and other purposes connected with the relief of sick and wounded.

"4. In removing sick and wounded the enlisted men detailed to attend ambulances, as above directed, will alone be permitted to accompany them, and that they may be recognized as having been appointed for this purpose, each of them will wear a white badge on the left arm above the elbow, the same to be provided by the Medical Department.

"5. Division Quartermasters will be responsible for all public property connected with said Division ambulance trains, and will exercise authority over all matters pertaining to the parking and preservation of the same.

"6. Army Corps commanders and Medical Directors of Army Corps will make such regulations for the removal of wounded and sick as will, in their judgment, best secure the end desired to be attained under this order.

"By order of Major-General U. S. GRANT.

(Signed) "JNO. A. RAWLINS,
"*Assistant Adjutant General.*"

Actual experience in the field suggested various changes in the original plan adopted in the Army of the Potomac, and on August 22, 1863, Surgeon Letterman laid before the General Commanding revised regulations, which were published in General Orders No. 85, Headquarters of the Army of the Potomac, August 24, 1863:

"The following revised regulations for the organization of the Ambulance Corps and the management of the ambulance trains are published in lieu of Special Orders No. 147, Headquarters Army of the Potomac, August 2, 1862, for the information and government of all concerned. Commanders of Army Corps will see that they are carried into effect.

"1. The Army Corps is the unit of organization for the Ambulance Corps, and the latter will be organized upon the basis of Captain as the Commandant of the Corps, one 1st Lieutenant for each Division, one 2d Lieutenant for each brigade, one sergeant for each regiment.

"2. The privates of this corps will consist of two men and one driver to each ambulance and one driver to each medicine wagon.

"3. The two-horse ambulances only will be used, and the allowance until further orders to each corps will be upon the basis of three to each regiment of infantry, two to each regiment of cavalry, one to each battery of artillery, to which it will be permanently attached, and two to the Headquarters of each Army Corps; and two army wagons to each Division. Each ambulance will be provided with two stretchers.

"4. The captain is the commander of all the ambulances, medicine, and other wagons in the corps, under the immediate direction of the Medical Director of the Army Corps to which the Ambulance Corps belongs. He will pay special attention to the condition of the ambulances, wagons, horses, harness, etc., and see that they are at all times in readiness for service, that the officers and men are properly instructed in their duties, and that these duties are performed, and that the regulations of the corps are strictly adhered to by those under his command. He will institute a drill in his corps, instructing his men in the most easy and expeditious method of putting men in and taking them out of the ambulances, lifting them from the ground, and placing and carrying them on stretchers, in the latter case observing that the front man steps off with the left foot and the rear man with the right, etc.; that in all cases his men treat the sick and wounded with gentleness and care; that the ambulances and wagons are at all times provided with attendants, drivers, horses, etc.; that the vessels for carrying water are constantly kept clean and filled with fresh water; that the ambulances are not used for any other purpose than that for which they are designed and ordered. Previous to a march he will receive from the Medical Director of the Army Corps his orders for the distribution of the ambulances for gathering up the sick, and previous to and in time of action he will receive orders from the same officer where to send his ambulances, and to what points the wounded are to be carried. He will give his personal attention to the removal of the sick and wounded from the field in time of action, going from place to place to ascertain what may be wanted, to see that his subordinates (for whose conduct he will be responsible) attend faithfully to their duties in taking care of the wounded and removing them as quickly as may be found consistent with their safety to the field hospitals, and see that the ambulances reach their destination. After every battle he will make a report, in detail, of the operations of his corps to the Medical Director of the Army Corps to which he belongs, who will transmit a copy with such remarks as he may deem proper to the Medical Director of this Army. He will give his personal attention to the removal of sick when they are required to be sent to general hospitals, or to other points as may be ordered. He will make a personal inspection at least once a month of everything pertaining to the Ambulance Corps, a report of which will be made to the Medical Director of the Corps, who will transmit a copy to the Medical Director of this Army. This inspection will be minute and made with care, and will not supersede the constant supervision which he must at all times exercise over his corps. He will also make a weekly report according to the prescribed form to the same officer, who will forward a copy to the Medical Director of this Army.

"5. The 1st lieutenant assigned to the Ambulance Corps for a Division will have complete control, under the captain of his corps and the Medical Director of the Army Corps, of all the ambulances, medical and other wagons, horses, etc., and men in that portion of the Ambulance Corps. He will be the Acting-Assistant Quartermaster for that portion of the corps, and will receipt for and be responsible for all the property belonging to it, and be held responsible for any deficiency in anything appertaining thereto. He will have a travelling cavalry forge, a blacksmith, and a saddler, who will be under his orders, to enable him to keep his train in order. His supplies will be drawn from the Depot Quartermaster upon requisitions approved by the captain of his corps and the Commander of the Army Corps to which he is attached. He will exercise a constant supervision over his train in every particular, and keep it at all times ready for service. Especially before a battle will he be careful that everything be in order. The responsible duties devolving upon him in time of action render it necessary that he be active and vigilant, and spare no labor in their execution. He will make reports to the captain of the corps upon the form prescribed every Saturday morning.

"6. The 2d lieutenant will have command of the portion of the Ambulance Corps for a brigade, and will be under the immediate orders of the commander of the ambulances for a Division, and the injunctions in regard to care and attention and supervision prescribed for the Commander of the Division he will exercise in that portion under his command.

"7. The sergeant will conduct the drills, inspections, etc., under the orders and supervision of the commander of the ambulances for a brigade, be particular in enforcing all orders he may receive from his superior officers, and that the men are attentive to their duties. The officers and non-commissioned officers will be mounted. The non-commissioned officers will be armed with revolvers.

"8. Two medical officers and two hospital stewards will be detailed daily by roster by the Surgeon-in-Chief of the Division, to accompany the ambulances for the Division when on the march, whose duties will be to attend to the sick and wounded with the ambulances and see that they are properly cared for. No man will be permitted by any line officer to fall to the rear to ride in the ambulances unless he has written permission from the senior medical officer of his regiment to do so. These passes will be carefully preserved, and at the close of march be transmitted by the senior medical officer with the train, with such remarks as he may deem proper, to the Surgeon-in-Chief of his Division. A man who is sick or wounded, who requires to be carried in an ambulance, will not be rejected; should he not have the permission required, the Surgeon of the regiment who has neglected to give it will be reported at the close of the march by the senior Surgeon with the train, to the Surgeon-in-Chief of his Division. When on the march, one-half the privates of the Ambulance Corps will accompany on foot the ambulances to which they belong, to render such assistance as may be required. The remainder will march in the rear of their respective commands to conduct, under the orders of the medical officers, such men as may be unable to proceed to the ambulances, or who may be incapable of taking proper care of themselves, until the ambulances come up. When the case is of so serious a nature as to require it, the Surgeon of the regiment or his assistant will remain and deliver the man to one of the medical officers with the ambulances. At all other times the privates will be with their respective trains. The medicine wagons will on the march be in their proper places in the rear of the ambulances for each brigade. Upon ordinary marches the ambulances and wagons belonging to the train will follow immediately in the rear of the Division to which it is attached. Officers connected with the corps must be with the trains when on the march, observing that no one rides in any of the ambulances except by authority of medical officers. Every necessary facility for taking care of the sick and wounded upon the march will be afforded the medical officers by the officers of the Ambulance Corps.

"9. When in camp the ambulances will be parked by division. The regular roll-calls, reveille, retreat, and tattoo will be held, at which at least one commissioned officer will be present and receive the reports. Stable duty will be at hours fixed by the captain of the corps, and at this time, while the drivers are in attendance upon their animals, the privates will be employed in keeping the ambulances to which they belong in order, keeping the vessels for carrying water filled with fresh water, and in general police duties. Should it become necessary for a regimental medical officer to use one or more ambulances for transporting sick and wounded, he will make a requisition upon the Commander of the Ambulances for a Division, who will comply with the requisition. In all cases when ambulances are used the officers, non-commissioned officers, and men belonging to them will accompany them; should one ambulance only be required, a non-commissioned officer as well as the men belonging to it will accompany it. The officers of the Ambulance Corps will see that ambulances are not used for any other purpose than that for which they are designed, viz: the transportation of sick and wounded, and in urgent cases only, of medical supplies. All officers are expressly forbidden to use them, or to require for them to be used for any other purpose. When ambulances are required for the transportation of sick or wounded at Division or Brigade Headquarters they will be obtained as they are needed for this purpose from the Division train, but no ambulances belonging to this corps will be retained at such headquarters.

"10. Good, serviceable horses will be used for the ambulances and medicine wagons, and will not be taken for any other purpose except by orders from these Headquarters.

"11. The corps will be designated, for sergeants, by a green band 1¼ inches broad around the cap, and chevrons of the same material, with the point toward the shoulder, on each arm above the elbow. For privates, by a band the same as for sergeants around the cap, and a half chevron of the same material on each arm above the elbow.

"12. No person except the proper medical officers or the officers and non-commissioned officers and privates of this corps will be permitted to take or accompany sick or wounded to the rear either on the march or upon the field of battle.

"13. No officer or man will be selected for this service except those who are active and efficient, and they will be detailed and relieved by Corps Commanders only.

"14. Corps Commanders will see that the foregoing regulations are carried into effect.

"BY COMMAND OF MAJOR GENERAL MEADE:

(Signed) "S. WILLIAMS,
"*Assistant Adjutant General.*"

The establishment of a uniform system of ambulance corps in the armies of the United States was not accomplished until the spring of 1864, when Congress[1] passed the following act, which was approved by the President on March 11, 1864, and promulgated by the Secretary of War in General Orders No. 106, War Department, A. G. O., Washington, D. C., March 16, 1864:

"*Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled*, That the medical director, or chief medical officer of each army corps, shall, under the control of the medical director of the army to which such army corps belongs, have the direction and supervision of all ambulances, medicine and other wagons, horses, mules, harness, and other fixtures appertaining thereto, and of all officers and men who may be detailed or employed to assist him in the management thereof, in the army in which he may be serving.

"SEC. 2. *And be it further enacted*, That the commanding officer of each army corps shall detail officers and enlisted men for service in the ambulance corps of such army corps, upon the

[1] A copy of the bill as originally introduced in Congress in the winter of 1863 to 1864, was submitted by the Committee on Military Affairs of the Senate to Surgeon LETTERMAN for recommendations and suggestions, and was returned by him with the following letter:

"HEADQUARTERS ARMY OF THE POTOMAC,
"MEDICAL DIRECTOR'S OFFICE, *January* 2, 1864.

"DEAR SIR: As desired by the clerk of the Committee on Military Affairs in the Senate, from whom, since I took the liberty of addressing you on the 31st ult., I received a copy of the bill in reference to an Ambulance System, I have the honor to submit for your consideration the following suggestions, viz: In SECTION 1, line 2, after the word 'shall' insert the words 'under the control of the Medical Director of the Army to which such Army Corps belongs.' This suggestion is made because it is considered necessary that there should be *one* officer who shall have the control and supervision of the Ambulance Corps throughout an army, and as the Medical Director of an army is held responsible for the care (in the widest meaning of the word) of the wounded and sick in that army, it is necessary that he should control the subordinate officers in his department, and his authority be commensurate with his responsibility. SECTION 1, line 4, after the word 'medicine' insert the words 'and other.' This will make the provisions of the bill harmonize. SECTION 2, line 2, after the word 'detail' insert the words 'officers and enlisted men.' SECTION 2, line 2, after the words 'Army Corps' insert the words 'upon the following basis, viz.' These alterations will, I think, clearly show that the officers and men are detached from their regiments, brigades, etc., and the Ambulance Corps in each Army Corps considered a unit, and as belonging not to any particular regiment, brigade, etc., but to the Army Corps at large, a feature very essential to the proper working of the system. SECTION 3. Strike out all after the word 'furnished,' in line 1, to the word 'and,' in line 7, and insert the words 'to each Army Corps two-horse ambulances upon the following basis, viz: three to each Regiment of Infantry; two to each Regiment of Cavalry; one to each Battery of Artillery; to which it shall be permanently attached.' The ground-work of the organization is to take from regiments the *direct* control of the ambulances and form them into trains under proper officers and men. Unless they are so they cannot be wielded with facility, kept in order, or be properly supervised by the superior medical officers. It has been found when ambulances are attached to regiments that they are of very little use, especially upon a march or in time of action—the regimental medical officers under such circumstances cannot, from the nature and pressure of their duties at such time, control them. The proposed alteration will harmonize with the provisions of SECTION 8. It is proposed to attach the ambulance to each battery, as the latter has no fixed position and is liable to constant change. I regard the last three suggestions as of vital importance to the successful working of the system. SECTION 3, line 8, after the word 'division' insert the words 'train of ambulances.' SECTION 5. Strike out all after the words 'Army Corps,' in line 15, to the words 'and it shall,' in line 18, and insert 'previous to a march, and previous to and in time of action, or whenever it may be necessary to use the ambulances, to issue the proper orders to the captain for the distribution and management of the same; for collecting the sick and wounded and conveying them to their destination.' SECTION 5, line 21, strike out all after the words 'Surgeon General' to the end of the section, and insert instead 'or the Medical Director of the Army; and all reports to higher authority than the Commanding Officer of the Army Corps shall be transmitted through the Medical Director of the Army to which such Army Corps belongs.' The Medical Director of an Army having, under the Commanding General, the control of the Ambulance Corps in all Army Corps, military subordination and discipline require all correspondence and reports to pass through him. The words that are proposed to be stricken out are not necessary, as the Commanding Officer of an Army Corps has all in his Corps under his supervision. SECTION 6. Strike out in line 7 the words 'of their respective regiments' and insert the words 'under his orders.' This is suggested that the different sections may be in harmony, and to reject the idea of the ambulances being attached to regiments. SECTION 8, line 3, strike out the word 'officers' and instead of it insert the word 'persons.' I have made the above suggestions freely and without reserve, as I believe you desire, and it is in accordance with my own wishes that my views be plainly given on the subject. The manner in which the ambulance trains are now established and conducted in this army permits the formation either of Corps, Division, or Regimental Hospitals, or the change from one to the other as the exigencies of the service may require at any time, without delay or inconvenience, and to the great advantage of the sick and wounded, and I am fully convinced from my experience that when properly carried into effect this system can be managed without trouble, and the sick and wounded, by their own officers, be promptly, carefully, and efficiently cared for, and thus, in no small degree, contributing to the efficiency of the army in which it is properly administered.

"I am, sir, very respectfully, your obedient servant,

(Signed) "JONATHAN LETTERMAN,
"*Medical Director.*

"Hon. HENRY WILSON,
"*U. S. Senate.*"

It will be noted that the suggestions of Dr. LETTERMAN were incorporated in the bill.

following basis, viz: one captain, who shall be commandant of said ambulance corps; one first lieutenant for each division in such army corps; one second lieutenant for each brigade in such army corps; one sergeant for each regiment in such army corps; three privates for each ambulance, and one private for each wagon; and the officers and non-commissioned officers of the ambulance corps shall be mounted: *Provided*, That the officers, non-commissioned officers, and privates so detailed for each army corps shall be examined by a board of medical officers of such army corps as to their fitness for such duty; and that such as are found to be not qualified shall be rejected, and others detailed in their stead.

"SEC. 3. *And be it further enacted*, That there shall be allowed and furnished to each army corps two-horse ambulances upon the following basis, to wit: three to each regiment of infantry of five hundred men or more; two to each regiment of more than two hundred and less than five hundred men or more; and one to each regiment of infantry of less than two hundred men; two to each regiment of cavalry of five hundred men or more; and one to each regiment of cavalry of less than five hundred men; one to each battery of artillery—to which battery of artillery it shall be permanently attached; to the headquarters of each army corps two such ambulances; and to each division train of ambulances two army wagons; and ambulances shall be allowed and furnished to division brigades and commands not attached to any army corps upon the same basis, and each ambulance shall be provided with such number of stretchers and other appliances as shall be prescribed by the Surgeon General: *Provided*, That the ambulances and wagons herein mentioned shall be furnished, as far as practicable, from the ambulances and wagons now in the service.

"SEC. 4. *And be it further enacted*, That horse and mule litters may be adopted or authorized by the Secretary of War, in lieu of ambulances, when judged necessary, under such rules and regulations as may be prescribed by the medical director of each army corps.

"SEC. 5. *And be it further enacted*, That the captain shall be the commander of all the ambulances, medicine and other wagons in the corps, under the immediate direction of the medical director, or chief medical officer, of the army corps to which the ambulance corps belongs. He shall pay special attention to the condition of the ambulances, wagons, horses, mules, harness, and other fixtures appertaining thereto, and see that they are at all times in readiness for service; that the officers and men of the ambulance corps are properly instructed in their duties, and that their duties are performed, and that the regulations which may be prescribed by the Secretary of War, or the Surgeon General, for the government of the ambulance corps are strictly observed by those under his command. It shall be his duty to institute a drill in his corps, instructing his men in the most easy and expeditious manner of moving the sick and wounded, and to require in all cases that the sick and wounded shall be treated with gentleness and care, and that the ambulances and wagons are at all times provided with attendants, drivers, horses, mules, and whatever may be necessary for their efficiency; and it shall be his duty also to see that the ambulances are not used for any other purpose than that for which they are designed and ordered. It shall be the duty of the medical director, or chief medical officer, of the army corps, previous to a march, and previous to and in time of action, or whenever it may be necessary to use the ambulances, to issue the proper orders to the captain for the distribution and management of the same, for collecting the sick and wounded and conveying them to their destination. And it shall be the duty of the captain faithfully and diligently to execute such orders. And the officers of the ambulance corps, including the medical director, shall make such reports, from time to time, as may be required by the Secretary of War, the Surgeon General, the medical director of the army, or the commanding officer of the army corps in which they may be serving; and all reports to higher authority than the commanding officer of the army corps shall be transmitted through the medical director of the army to which such army corps belongs.

"SEC. 6. *And be it further enacted*, That the first lieutenant assigned to the ambulance corps for a division shall have complete control, under the captain of his corps and the medical director of the army corps, of all the ambulances, medicine and other wagons, horses, mules, and men in that portion of the ambulance corps. He shall be the acting assistant quartermaster for that portion of the ambulance corps, and will receipt for and be responsible for all the property belonging to it, and be held responsible for any deficiency in anything appertaining thereto. He shall have a travelling cavalry forge, a blacksmith, and a saddler, who shall be under his orders, to enable him to keep his train in order. He shall have authority to draw supplies from the depot quartermaster,

upon requisitions approved by the captain of his corps, the medical director, and the commander of the army corps to which he is attached. It shall be his duty to exercise a constant supervision over his train in every particular, and keep it at all times ready for service.

"SEC. 7. *And be it further enacted*, That the 2d lieutenant shall have command of the portion of the ambulance corps for a brigade, and shall be under the immediate orders of the 1st lieutenant, and he shall exercise a careful supervision over the sergeants and privates assigned to the portion of the ambulance corps for his brigade; and it shall be the duty of the sergeants to conduct the drills and inspections of the ambulances, under his orders, of their respective regiments.

"SEC. 8. *And be it further enacted*, That the ambulances in the armies of the United States shall be used only for the transportation of the sick and wounded, and, in urgent cases only, for medical supplies, and all persons shall be prohibited from using them, or requiring them to be used, for any other purpose. It shall be the duty of the officers of the ambulance corps to report to the commander of the army corps any violation of the provisions of this section, or any attempt to violate the same. And any officer who shall use an ambulance, or require it to be used, for any other purpose than as provided in this section, shall, for the first offense, be publicly reprimanded by the commander of the army corps in which he may be serving, and for the second offense shall be dismissed from the service.

"SEC. 9. *And be it further enacted*, That no person except the proper medical officers, or the officers, non-commissioned officers, and privates of the ambulance corps, or such persons as may be specially assigned, by competent military authority, to duty with the ambulance corps for the occasion, shall be permitted to take or accompany sick or wounded men to the rear, either on the march or upon the field of battle.

"SEC. 10. *And be it further enacted*, That the officers, non-commissioned officers, and privates of the ambulance corps shall be designated by such uniform or in such manner as the Secretary of War shall deem proper. *Provided*, That officers and men may be relieved from service in said corps and others detailed to the same, subject to the examination provided in the second section of this act, in the discretion of the commanders of the armies in which they may be serving.

"SEC. 11. *And be it further enacted*, That it shall be the duty of the commander of the army corps to transmit to the Adjutant General the names and rank of all officers and enlisted men detailed for service in the ambulance corps of such army corps, stating the organizations from which they may have been so detailed; and, if such officers and men belong to volunteer organizations, the Adjutant General shall thereupon notify the governors of the several States in which such organizations were raised of their detail for such service; and it shall be the duty of the commander of the army corps to report to the Adjutant General from time to time the conduct and behavior of the officers and enlisted men of the ambulance corps, and the Adjutant General shall forward copies of such reports, so far as they relate to officers and enlisted men of volunteer organizations, to the governors of the States in which such organizations were raised.

"SEC. 12. *And be it further enacted*, That nothing in this act shall be construed to diminish or impair the rightful authority of commanders of armies, army corps, or separate detachments, over the medical and other officers and the non-commissioned officers and privates of their respective commands.

"*Approved March* 11, 1864."

By the passage of this act the authority of the Medical Department over the Ambulance Corps was fully established. How effectually, and at the same time how considerately, the medical officers availed themselves of the power thus conferred upon them is strikingly shown in the systematic manner with which the immense number of wounded after the battles of the Wilderness, Spottsylvania Court House, Cold Harbor, Petersburg, and of the campaign in Georgia and the Carolinas, were cared for on the battle-field, were removed to field and base hospitals, and were finally distributed in general hospitals throughout all parts of the United States. Notwithstanding the opinion of General H. W. Halleck, no *panics* or *stampedes* were reported as having been caused by the presence of the non-combatants of the ambulance corps.

AMBULANCE WAGONS.

Ambulance wagons, or wagons especially designed for the transport of sick and wounded, had not been in use in the armies of the United States until a year or so before the outbreak of the War of the Rebellion. Transport carts, army wagons, ox teams, in fact anything that could be made available for the purpose, had been employed. In the War of Independence, in April, 1777, the Congress of the United States passed a bill "devising ways and means for preserving the health of the troops" which contained the following paragraph:[1] "That a suitable number of covered and other wagons, litters, and other necessaries for removing the sick and wounded, shall be supplied by the Quartermaster or Deputy Quartermaster General; and in case of their deficiency, by the Director or Deputy Director General." There is no record that such vehicles were supplied. During the war with Great Britain, in 1812–'14, there were evidently no ambulance wagons in the United States army, as Surgeon James Mann,[2] in his report of that campaign, is found to make the request that, "to facilitate the movement of the hospital department attached to an army, it should be furnished with a number of wagons and teams, so as not to be immediately dependent on the Quartermaster's Department, when requisite either to take the wounded from the field of battle, or transport the sick in case of a retrograde march, or remove invalids after having recovered from wounds to a remote hospital. The flying machines called *volantes*, drawn by horses (an improvement of Larrey, Chief Surgeon of the French army), are useful in open countries, where a corps is assigned to accompany them on the field of battle, upon Larrey's plan." The same author (*loc. cit.*, p. 126) relates that he transported, in February, 1814, four hundred and fifty sick men from Malone to Plattsburgh and Burlington, a distance of seventy miles, in sleighs, losing six patients by death. In the Florida war, in 1838, ambulance wagons are mentioned by Surgeon R. S. Satterlee, U. S. A., Medical Director south of Withlacoochee, in a report from Fort Brooke, Tampa Bay, dated January 5th: "I found the ambulances very serviceable, but as some of the wounded could not be transported in them, on account of the roughness of the road, between thirty and forty of them were brought a part of the way on litters between two horses." Surgeon Satterlee probably had reference to the ordinary transport wagons used on this occasion for conveying sick and wounded.

In the *General Regulations for the Army of the United States*, Washington, 1847, page 123, paragraph 704, it was ordered that: "For the accommodation of the sick and disabled, a wagon will be attached to the rear guard, when necessary and practicable, and a surgeon will attend to give assistance, and to see that no improper persons are suffered to avail themselves of the accommodation." No ambulance wagons were attached to the American army in Mexico in 1846–'48, or to the expeditions in Indian territories before the outbreak of the war.

In 1858 an ambulance wagon (FIGS. 452, 453) had been proposed by Dr. I. Moses, of New York, and on March 2, 1858, a Board of Officers, consisting of Surgeons R. S. Satterlee, C. H. Laub, and Assistant Surgeon C. H. Crane, had been appointed to examine and report on its merits. The report of the Board is appended: "The ambulance resembles an omnibus, is entered by two steps in the rear, contains seats for eighteen persons—fourteen inside and four on the front seat. By raising the flaps of the inside seats and supporting them by the

uprights attached, and removing the cushions from the backs of the permanent seats, a bed is arranged which will accommodate *one*, *two*, or, on an emergency, *three* men lying down. With *one* man in a recumbent position, room for *twelve* men seated remains; with *two* men lying down, room for *eight*, and with *three* men lying down, room for *six* remains. A

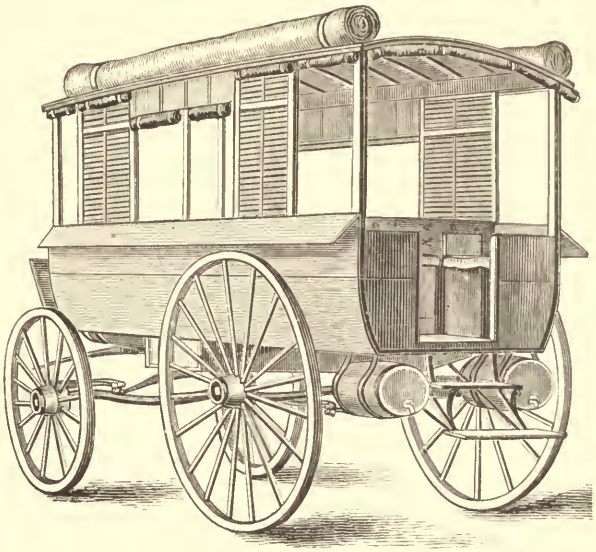

FIG. 453.—The "MOSES" ambulance wagon—rear view.

canvas, stretched and suspended by cords from the top, will accommodate two men lying down where the roads are rough. A close-stool is provided in the vehicle. Two seats, separated from the rest, next to the door, are provided for the hospital steward and attendant. Two movable chests are placed under these seats to contain what may be required for daily use. The movable door closing the ambulance may become, by change of position, a table for writing or dispensing medicine. The interior is closed entirely by curtains of prepared canvas, or partly by curtains and Venetian blinds for free ventilation—windows admitting sufficient light when entirely closed. Under the front seat are placed two store chests. Underneath the carriage, on either side of the door, are two five-gallon kegs for water. Under the body of the vehicle are hooks for camp kettles, pails, and cooking utensils. Two drawers are arranged on each side, between the wheels and under the carriage, which may be used as panniers when necessary. On the hooks surrounding the ambulance, five feet from the ground, canvas is stretched, extending ten feet on *each* side of the carriage, the front and rear being protected in the same manner, which forms a comfortable and ample tent protec-

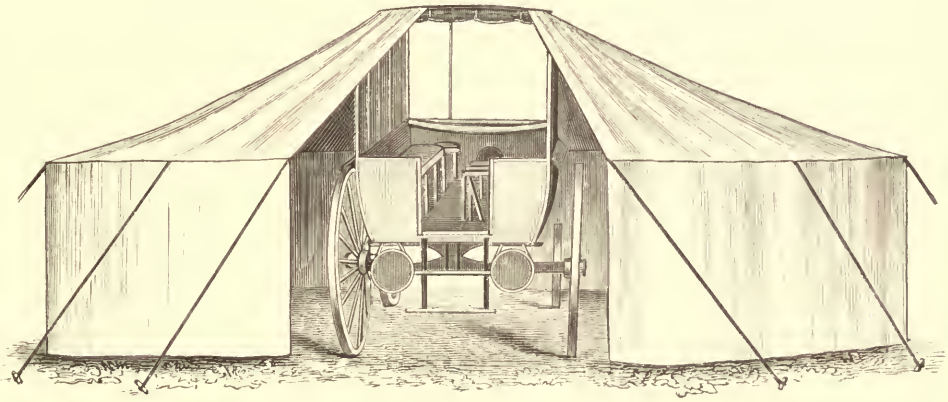

FIG. 454.—The "MOSES" ambulance wagon and tent.

tion for *thirty* sick men, and which may be arranged in a few minutes after arriving in camp by one or two men. In more permanent encampments, or in hot weather, this canvas may be fastened to hooks around the top of the ambulance wagon (FIG. 454), serving a better purpose by giving more space and freer ventilation. It is suggested that a light iron railing, about four inches in height, should surround the top of the ambulance, where, by having a suitable canvas cover, blankets and other indispensable articles might be securely carried. A lantern suspended over the front seat may be removed to the rear of the carriage, at will. It will admit of sufficient accommodation in the way of transportation and provide tent shelter for the sick of a regiment on marches. The dimensions are: extreme length, thirteen feet eight inches; height of floor from ground, three feet three inches; height of top from ground, eight feet four inches; height of inside, five feet; width, four feet four inches. Weight, two thousand one hundred and fifteen (2,115) pounds. When loaded with men, medicines, tent canvas, etc., it can be readily drawn by six horses or mules. The size of the wheels and the track of the same correspond with those of the government wagons. After a close examination of the ambulance, the Board is of the opinion that it is well adapted for field and frontier service, and for the comfortable transportation of sick and wounded men on long marches; that the tent arrangement forms a valuable, useful, and comfortable shelter for hospital patients. On marches it does away with the use of hospital tents, is easily arranged, keeps the hospital separate, and requires no detail of pioneers or extra duty men to pitch and arrange it. In submitting this opinion the members of the Board must also express their views, based upon their own individual experience, that to be made thus available and useful for the comfort and well-being of the sick the ambulance should be the property of the Medical Department, and that the team, harness, etc., should be under the exclusive control and direction of the medical officers under all and every circumstance." No action seems to have followed the recommendations of this Board, and no ambulances were built.

In October, 1859, a Board of Medical Officers, consisting of Surgeon C. A. Finley, R.

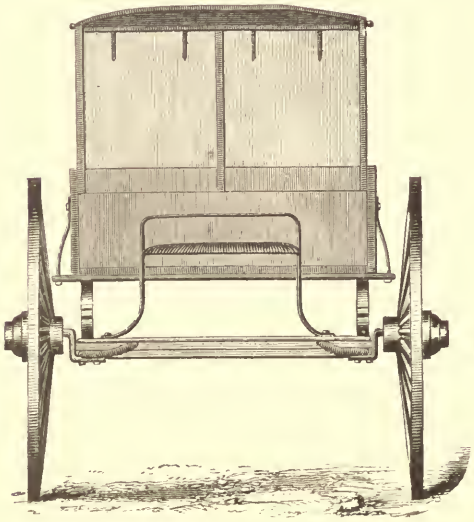

FIG. 455.—The "FINLEY" two-wheeled ambulance wagon—front view.

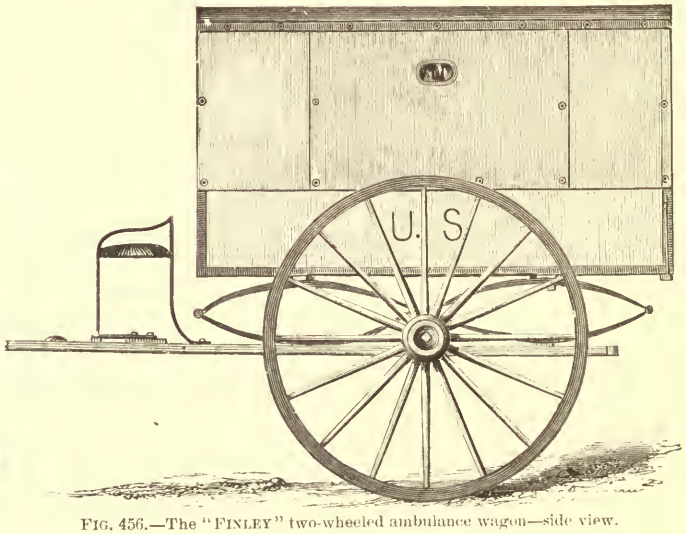

FIG. 456.—The "FINLEY" two-wheeled ambulance wagon—side view.

S. Satterlee, C. S. Tripler, J. M. Cuyler, and Assistant Surgeon R. H. Coolidge, had recommended: 1st, that ambulance transportation ought to be furnished for forty men per thousand—twenty lying extended and twenty sitting; 2d, that both two and four-wheeled

ambulance wagons are necessary for the hospital service; 3d, that a two-wheeled ambulance wagon is the best for the conveyance of dangerously sick or wounded men * * *; that to each company one two-wheeled ambulance wagon, to a battalion of five companies one four-wheeled and five two-wheeled ambulance wagons, and to a regiment two four-wheeled and ten two-wheeled ambulance wagons be allowed; and that for hospital supplies to commands of less than three companies one two-wheeled transport cart, to commands of more than three or less than five, or five companies, two, and to a regiment four two-wheeled transport carts be assigned; and that the transport carts be made after the models of the two-wheeled ambulance wagons (their interior arrangement for the sick excepted). The same Board selected, from a number of the most approved plans laid before them, the two-wheeled wagons designed by Surgeon C. A. Finley and Assistant Surgeon R. H. Coolidge. The bottom of the body of the Finley pattern (FIGS. 455, 456) was divided into two compartments, each containing a movable mattress frame or stretcher; four longitudinal pieces either in or upon the frame-work were grooved on their upper surfaces so as to receive the rollers in the mattress frame. The body of the wagon rested on four elliptical springs fastened upon the shafts, which extended the whole length of the body, crossing, and connected with the axle. The body

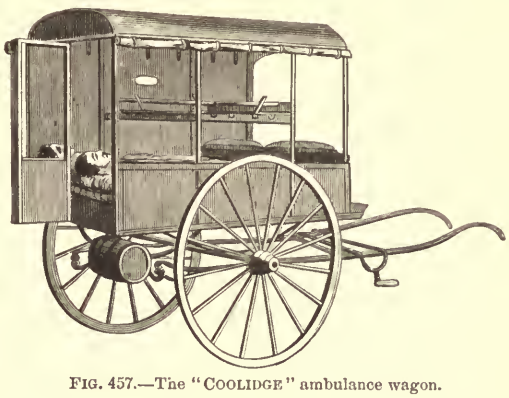

FIG. 457.—The "COOLIDGE" ambulance wagon.

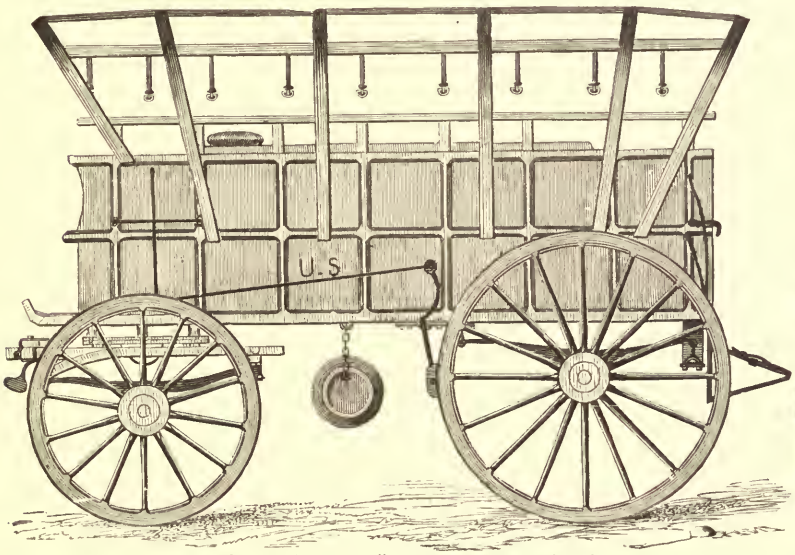

FIG. 458.—The "TRIPLER" ambulance wagon—side view.

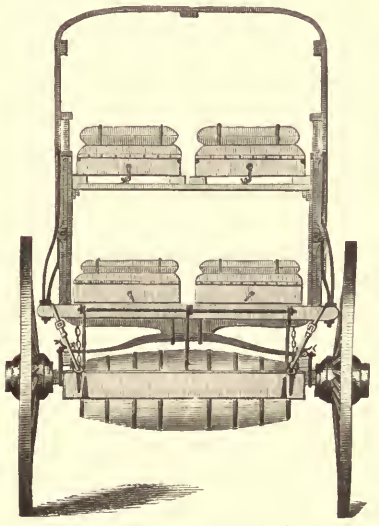

FIG. 459.—The same—rear view.

of the Coolidge cart (FIG. 457) was hung on platform springs. The body was seven feet long, four feet wide, and one foot and eight inches deep, covered with a ribbed frame-work five and a half inches above the floor. Upon the relative merits of the two patterns of two-wheeled ambulance carts the Board hesitated to express an opinion, and therefore recommended "that one of each pattern be sent to the respective Military Departments of Texas, New Mexico, Utah, California, and Oregon, and two of each pattern to Fort Leavenworth, and that they be placed in service at the scene of Indian hostilities and on marches across the plains, in order that their practical advantages might be ascertained." The Board con-

sidered the two-wheeled cart as the most convenient for the conveyance of dangerously sick and dangerously wounded men. A number of these two-wheeled carts[1] were furnished to the troops in the early part of the war, but experience soon proved them useless; their motion was intolerable and excruciating; wounded men begged to be taken out, wounded officers insisted upon leaving them, and they were supplanted by four-wheeled vehicles, the earliest of which was the Tripler ambulance wagon recommended by the Medical Board of 1859 (FIGS. 458–460).

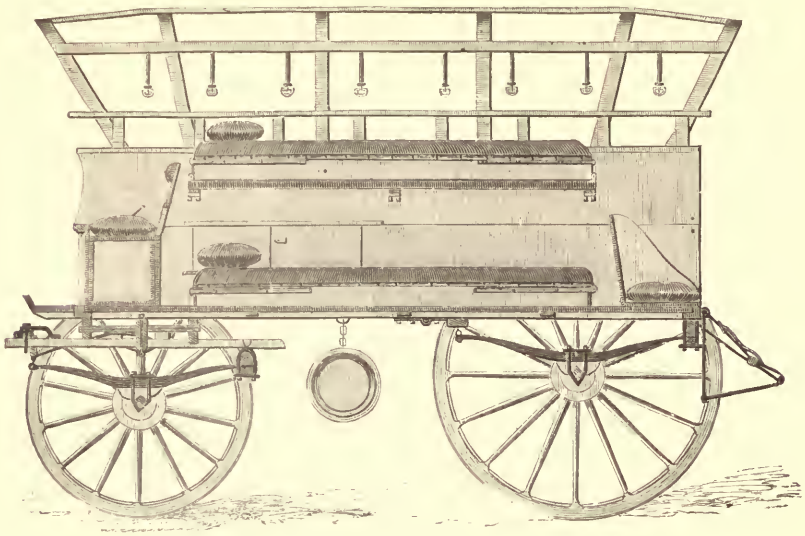

FIG. 460.—The "TRIPLER" ambulance wagon—longitudinal section.

It was constructed to carry ten men,[2] four lying at length and six seated, and required four horses. The body of the wagon was ten feet long, four feet wide, and the sides three feet high. Upon the floor were permanently laid four parallel iron rails seven feet long and one-fourth of an inch wide and high, with convex faces. Two spring mattresses were run in upon these rails. Twenty-two inches above the surfaces of these mattresses another set of rails was fitted to the wagon, upon which another set of mattresses was run. In front of the wagon was a chest intended for instruments, dressings, etc., which, when closed, formed a seat for three persons. At the tail of the carriage was another seat for three persons. All or any part of the interior of

FIG. 461.—The "WHEELING" or "ROSECRANS" ambulance wagon.

[1] On May 20, 1861, Acting Surgeon General R. C. WOOD wrote to the Secretary of War: "It is highly important that provision be made for the safe and comfortable transportation of the sick and wounded, and in conformity with the recommendations of a Board of Medical Officers convened by the Secretary of War, and their report approved by him in General Orders No. 1, January 19, 1860, I have to recommend that . . . two hundred of the two-wheeled ambulances be immediately constructed by the Quartermaster's Department. The recommendation was approved by the Secretary of War and the wagons were constructed and sent to the troops."

[2] LONGMORE (T.) (*A Treatise on the Transport of Sick and Wounded Troops*, London, 1869, page 382) erroneously states that this wagon was constructed to carry eight men, all lying down.

the wagon was arranged so that it could be removed at pleasure, making it available for the transportation of hospital supplies. The cover of the wagon was of heavy duck supported on five hoops. The carriage was hung on platform springs, and underneath the body was suspended a water-butt three feet six inches long and fourteen inches in diameter. This wagon was extensively used and answered the purpose, although it was cumbrous and very heavy.[1]

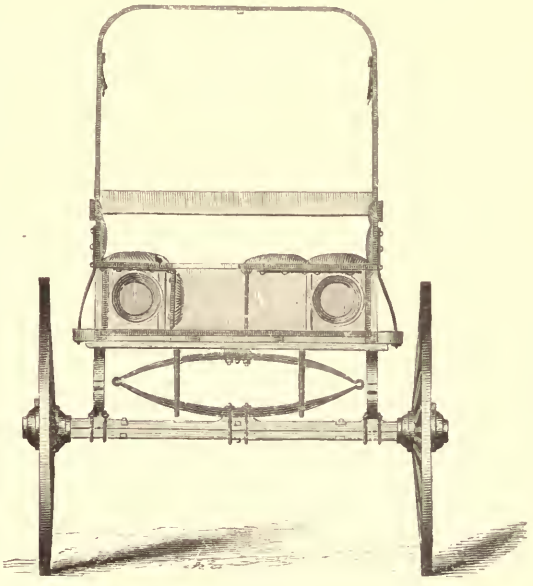

FIG. 462.—The same—rear view.

The Wheeling or Rosecrans ambulance wagon (FIGS. 461, 462) was also used in the early part of the war. It was built in the Government workshops after a design of General W. S. Rosecrans, U. S. A. It was lighter than the Tripler or the Coolidge, could be readily drawn by two horses, and would accommodate eleven or twelve sitting or two recumbent and two or three sitting patients. Two cushioned benches were attached to the two sides of the interior of the wagon, running along its whole length. From the edge of each of these benches, fastened by hinges, depended a cushioned seat the length of the benches. These seats could be readily brought on a level with the benches, and when thus elevated could be securely fixed by iron feet, folded in the suspended seat. For the ends of the iron feet receptacles were fitted in the floor of the wagon. When both seats were raised they met in the middle of the carriage and made one continuous bed for two patients. When only one seat was raised it formed a bed for a recumbent patient, while the other bench, with its suspended seat, allowed space for at least four sitting patients. A water-tank, capable of holding five gallons, was stored away under the seats in the rear end of the ambulance wagon; not unfrequently stretchers took the place of one of the water-tanks. In front of the benches a transverse seat, accommodating the driver and two or three patients, was

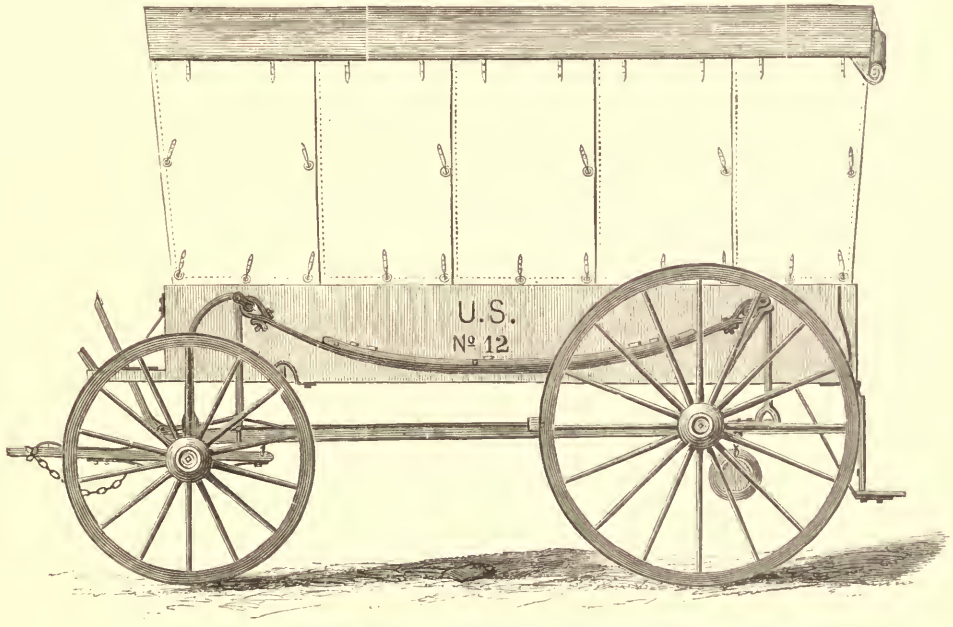

FIG. 463.—New COOLIDGE ambulance wagon—side view.

[1] Detailed specifications for the TRIPLER ambulance wagon will be found in a *Report of a Board of Officers to decide upon a Pattern of Ambulance Wagon for Army Use*. Washington, 1878. page 50.

provided. Under the seat was a box for medicines and other articles for field use. Accurate specifications for the building of this ambulance will be found on page 59 of the Report of a Board of Officers to decide upon a pattern of ambulance wagon above referred to. The body of the wagon rested upon four elliptical springs, two placed transversely (one on the front and one on rear axle), and two on the rear axle running longitudinally. A frame of light wood, with canvas cover, protected the patients against the inclemencies of the weather, and on the sides curtains of canvas could be closely buttoned to the top and the body. At the rear of the wagon was a step to assist patients and bearers in lifting in the wounded. The weight of the wagon was between seven hundred and eight hundred pounds.

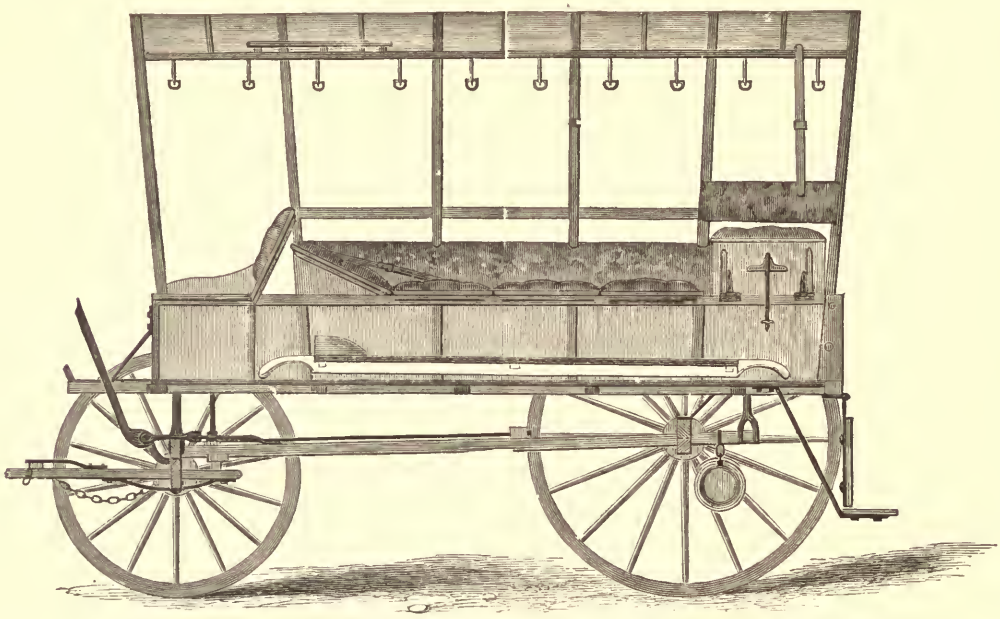

FIG. 464.—New COOLIDGE ambulance wagon arranged for two recumbent patients—perpendicular section.

A four-wheeled ambulance wagon (FIGS. 463, 464), designed by Assistant Surgeon R. H. Coolidge, was very little used. The sills of the wagon were ten feet four inches long, and the body rested between two semi-elliptical springs seven feet nine and three-quarter inches in length (FIG. 463). It was intended to accommodate two patients in recumbent and four in sitting postures, two with the driver on the front seat, and two at the end of the wagon, one on each side (see FIG. 465). The beds for the two prone patients

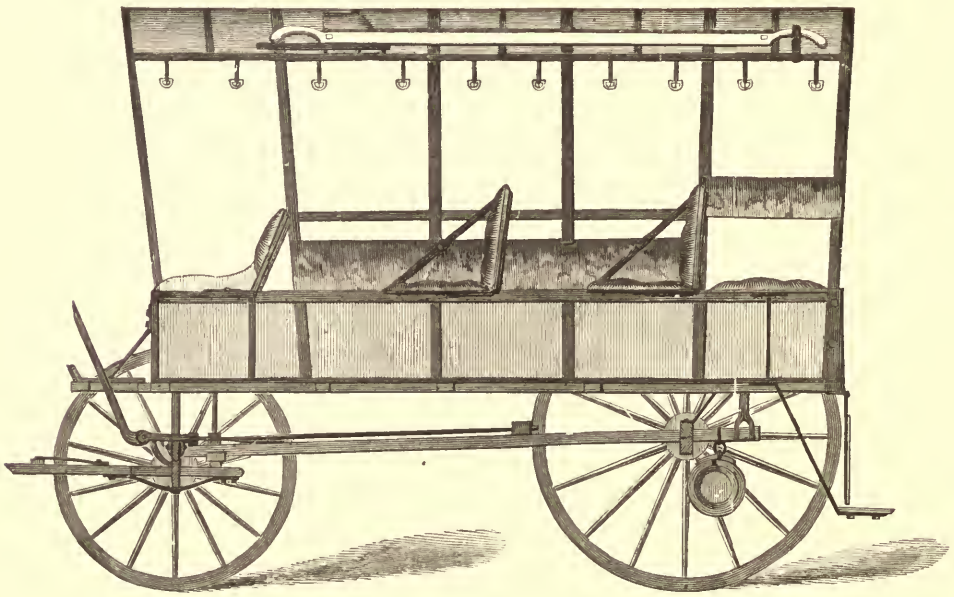

FIG. 465.—New "COOLIDGE" ambulance wagon arranged for sitting patients—perpendicular section.

were so arranged that they could be changed into seats, as shown in FIG. 465, when the wagon would accommodate ten patients and the driver. Detailed specifications of this ambulance wagon will be found on page 61 of the Report of a Board of Officers to decide upon a pattern of ambulance wagon already referred to.

Other plans for ambulance wagons were proposed during the war, and for the information of those interested in this subject we will here refer to such as were submitted to boards of medical officers for examination and report. In June, 1863, A. W. Süs (*Subject-Matter Index of Patents for Inventions issued by the United States Patent Office*, Washington, 1874, Vol. I, page 14, No. 39,595) exhibited a wagon intended to carry four severely wounded men in a recumbent position. A Medical Board (Medical Inspectors E. P. Vollum and W. H. Mussey, and Surgeon J. H. Brinton, U. S. V.) considered an "increase in the carrying capacity advantageous and feasible," but was not prepared to endorse the plan of Mr. Süs in all its details. The Board was of the opinion that the Wheeling ambulance wagon, then largely in use in the army, could readily be altered to carry four patients in a lying position, as in Mr. Süs's plan. Mr. Süs, in April, 1864, offered an improved plan, which was, by order of Surgeon R. O. Abbott, Medical Director, Department of Washington, inspected by Assistant Surgeon W. E. Waters, U. S. Army, who reported, on June 2, 1864: "These improvements consist in adapting the ambulance for the conveyance of four patients lying down, instead of two, as with the present arrangement, while, at the same time, the carrying capacity for such as can sit up is not at all interfered with. The improvement is effected by having the seats fastened with hooks to the side of the ambulance so that they can be detached and put upon the floor, thus forming a bed, on which the patient can lie with full as much comfort, as regards position, as with the present arrangement, while they are made more comfortable by the addition of elastic springs within the cushion." Surgeon Waters' report was approved by Medical Director Abbott, who recommended that ten or twelve ambulances fitted with these improvements be sent to the field for trial. In April, 1864, G. W. Arnold (*Subject-Matter Index of Patents, etc.*, page 14, No. 45,152) brought to the notice of the Surgeon General an ambulance wagon for which he claimed advantages over the Wheeling ambulance wagon in the arrangements of the seats or beds. The Board (Surgeon O. A. Judson and Assistant Surgeon W. Thomson) to whom the examination of the vehicle was referred reported, on April 5, 1864, that "the only advantages it possessed over the Wheeling model was that its litters could be removed from the wagon, the patient placed upon them, and then easily returned; but that the capacity for carrying men was diminished, and that the litters accompanying the wagon were too heavy, weighing about seventy pounds each, and would add, with their apparatus for suspension, nearly two hundred pounds to the weight of the ambulance wagon." On October 11, 1864, E. R. McKean patented an ambulance wagon (*Subject-Matter Index of Patents, etc.*, page 14, No. 44,643) with litters or beds suspended by rubber rings. Surgeons R. O. Abbott, C. Sutherland, and Assistant Surgeon William Thomson inspected the wagon and reported, on March 25, 1865: "The principle of suspending the stretcher upon which the patient lies by rings of India rubber, in lieu of the springs of steel usually placed beneath the body of the wagon, is the main difference between this and the ambulance now in general use. However valuable this principle may be, the mechanical contrivances by which it is obtained in the wagon submitted are, in the opinion of the Board, too complicated, wanting in solidity and durability, and too liable to the loss of detached pieces, to render this ambulance fit for the severe test of field service." In September, 1865, an India rub-

ber spring ambulance wagon, by Perot & Co., was brought to the attention of the Surgeon General by Brigadier General C. H. Crossman, U. S. Army. Surgeons C. McDougall, John Campbell, and A. K. Smith, and Assistant Surgeon C. H. Alden, appointed a Board to examine the rubber spring wagon, reported, on October 26, 1865: "The Board is very favorably impressed with the plan proposed, and as its peculiarities are best shown by contrast, would state the following as some of the particulars in which it is thought the India rubber spring is superior to the ordinary steel spring. It more perfectly controls the movements of the body of the ambulance in every direction, either upward, downward, or laterally, rendering the motion of those seated or lying within steadier and more equable. It is better adapted to carrying weights in the ambulance, acting with nearly the same effect with a light or heavy load. It is believed to be more durable. An ambulance built upon this plan was shown to the Board, belonging to the West Philadelphia Fire Company, which had been in use for several years, and which showed but little evidence of wear in the springs. It is easily repairable, as a spare spring can be readily carried in the ambulance wagon, and can be substituted for a broken one with but little delay and trouble. The India rubber springs weigh thirty-five and three-quarter pounds, which at seventy-five cents per pound would amount to $26.81. Steel springs of the same power would weigh about two hundred pounds and cost about $50.00."

The most serviceable ambulance wagon used during the latter part of the war was that designed by Brigadier General D. H. Rucker, and built at the Government repair shops at Washington. It accommodates patients either in the sitting or lying postures. On the floor of the vehicle are two stretchers suitable for carrying one patient each, and each divided by a longitudinal hinge-joint. These stretchers have the usual handles, and run on elastic rollers so as to move readily longitudinally in the bottom of the wagon. When required as seats, the joints of the stretchers are bent, and the two parts are made to assume (see FIG. 469) a position at right angles to each other, the half which has the horizontal position being hooked to the sides of the vehicle, the other part forming the support or leg for the front of the seat. When the lower bed or stretcher is thus bent to form a seat, the upper beds are turned down to make backs for the lower seats (see FIG. 469). These backs are only joined to the sides of the wagon by hinges at their upper edge, and the lower edge can be raised upward and inward, toward the middle of the carriage. When thus elevated the two backs meet in the middle of the carriage and are there supported by iron supports, which, being hinged to their under surfaces, can be readily lowered for the purpose. In the floor are springs for the reception of

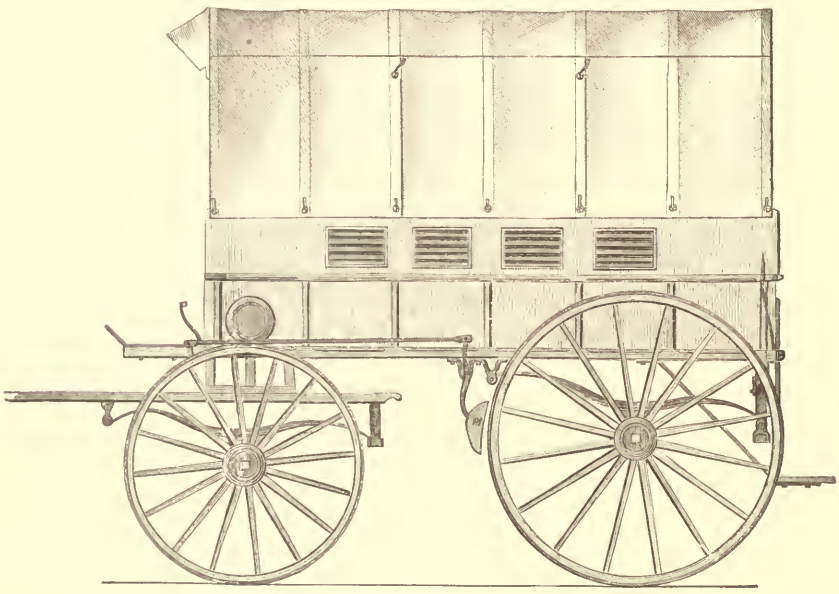

FIG. 466.—The "RUCKER" ambulance wagon.

the iron supports. A platform is thus built on which two patients, on stretchers, can be laid (FIG. 468). These stretchers ordinarily are suspended from the roof of the carriage, each stretcher being slung with one side to the middle of the roof and with the other to the bend of the arched roof (see FIG. 469). The space between the upper surface of the lower and the lower surface of the upper stretchers was about twenty-one inches. This space was ventilated by lattice openings on each side of the body of the ambulance wagon, as indicated in FIG. 466. The body rested on platform springs, and the fore wheels were smaller than the hind wheels. The water-cask was under the driver's seat, and the spigot projected slightly through the side of the body. The weight was about one thousand one hundred and twenty pounds, exceeding that of the Wheeling, which only weighed from seven to eight hundred pounds, but the Rucker wagon was somewhat longer and broader. Detailed specifications of this ambulance wagon will be found on page 48 of the *Report of a Board of Officers to decide upon a Pattern of Ambulance Wagon for Army Use*, Washington, 1878.

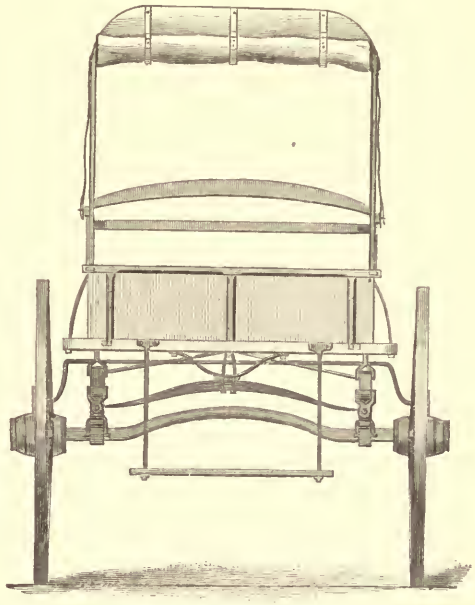

FIG. 467.—The same—rear view.

In October, 1864, Assistant Surgeon B. Howard, U. S. Army, constructed an ambulance wagon (FIGS. 470, 471) for which he claimed many advantages. A full description, with illustrations, will be found on pages 981–994 of *The Sanitary Commission Bulletin*, Vol. I, 1866; an extract, omitting some of the minor details, is here reproduced: "To enable the badly wounded to be easily loaded and unloaded, two litters or beds are provided, made of wood, like an ordinary shutter, with sliding handles at each corner. Upon this the patient is easily shifted, and without any disturbance. The litter is slid into the ambulance wagon on rollers. In the same way the patient is removed on arrival at the hospital, and without being disturbed until he reaches his bed. If part, or all the patients are able to sit up, one or both of the litters can be slid into a compartment provided for that purpose under the floor of the vehicle. There are six permanent seats, each situated transversely, and each a corner seat with back and cushioned seats. This gives a comfortable purchase, secures the patients against much of the usual jolting, and prevents them being driven against each other in going over rough roads. The sides of the

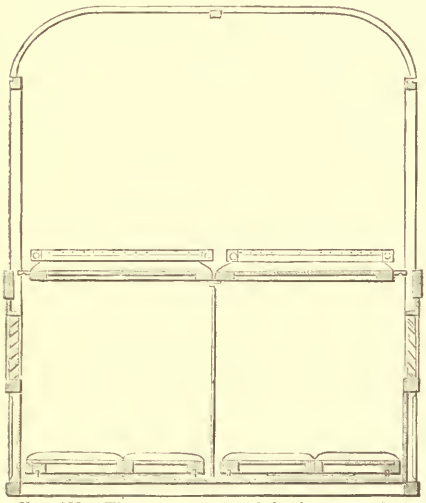

FIG. 468.—The same—arranged for four recumbent patients.

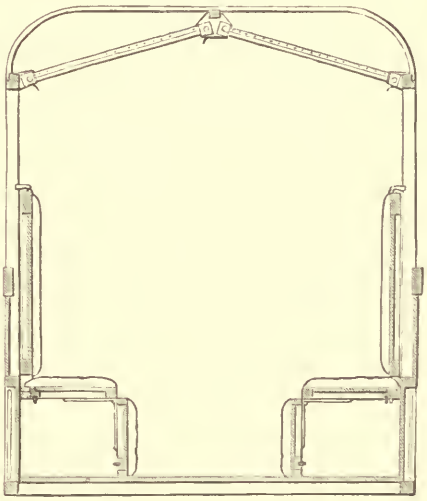

FIG. 469.—The body of the "RUCKER" ambulance wagon arranged for ordinary use.

ambulance wagon, as also both sides of the back of the driver's seat, and the inside of the upper section of the tail-board, are cushioned, while the middle seats have for a back a leather strap, like that used in stage coaches; thus each seat is rendered very comfortable, and being transverse instead of longitudinal is in every respect easier for the patient. In order to diminish the motion of the body of the wagon and prevent rolling and pitching, so intolerable in the ordinary ambulance wagon, semi-elliptical springs have been substituted for the elliptical ones.. In order that the limited motion

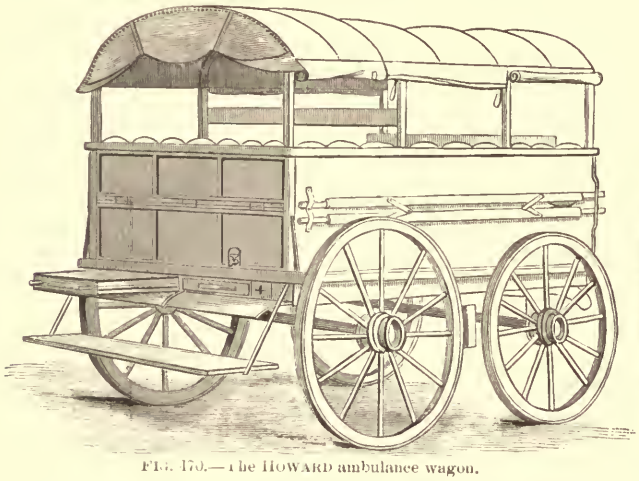

FIG. 470.—The HOWARD ambulance wagon.

FIG. 471.—The same—rear view.

thus obtained be so modified as to give least jar to patients, internal counterpoise springs are used, the delicacy of which may be modified to any extent desired. The platform or frame on which the seats and beds rest is as long but not so wide by about two inches as the inside of the body of the wagon. Between the inside of the body and the frame of the platform is an interspace; this is occupied by two lateral semi-elliptical steel springs on either side, fastened at the centre of their arc to the inside of the body of the vehicle, the feet of which play upon iron plates on the outside of the frame. Opposite the centre of the arc on the frame is fixed a block of soft rubber, so that on the application of much force it should be received by the rubber blocks, which thus act as buffers. The platform or frame on which the seats and beds rest stands upon four iron stanchions, each of which rests on springs like the lateral springs described above, but much stronger, as seen at FIG. 472, the iron stanchions resting on steel springs, the feet of which play upon iron plates let into the floor of the ambulance wagon. The spring is restrained in its motion upward by an iron staple, and when, by an unusual weight, it is heavily pressed down, the force is received by a block of soft India rubber enclosed within the staple. An impulse communicated to the floor of the wagon, instead of being propagated to the beds or seats, causes a counteraction downward of the spring, which, if the force be very great, spends itself upon the block of rubber. In this way, both laterally and perpendicularly, a constant poise is preserved, and what would otherwise be a very violent jar is reduced to little more than a vibration. The steadiness of the entire vehicle is preserved by the stout semi-elliptical spring beneath the body, and the delicacy regulated to any degree by the internal counterpoise springs within the body. That the water may be carried securely, immobility of the vessel containing it during transportation is neces-

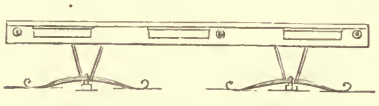

FIG. 472.—Springs for bed or litter frame.

sary. This is effected by substituting for the casks in ordinary use a tank, which slides into a grooved bed and is secured by an ordinary fastening. In a military point of view it possesses a great advantage in this: that besides the prescribed articles which may be carried in the driver's box, a large amount of medical supplies may be carried in the body of the ambulance wagon without interfering with the comfort of badly wounded patients. There being but four stanchions, and these being close up to the side of the vehicle, the entire body beneath the platform is free for transportation of supplies. There is an arrangement for suspension of fractures of the lower extremity, which is very grateful to the patients. Two parallel iron bars are attached to the roof of the ambulance wagon longitudinally over each bed, between which runs a roller with a dependent hook. The fractured limb being placed in a double-inclined plane or other splint, a bandage is passed through terrestra of the box splint and then carried over the hook from which the limb is suspended. In this way, instead of the jolting and jarring so commonly experienced, simple oscillation is substituted, or, if desired, guys of bandage may be so extended to the uprights of the ambulance as to render the limb nearly motionless during transportation."

The weight of the Howard ambulance wagon was twelve hundred and thirty-two pounds. The plan of this wagon, with recommendations of some twenty officers of the Army of the Potomac, was submitted for examination by Surgeon T. A. McParlin, Medical Director of the Fifth Army Corps, to a Board of Medical Officers, consisting of Surgeon J. J. Milhau, U. S. A., Surgeon L. W. Read, U. S. V., and Assistant Surgeon George A. McGill, U. S. A., who reported, on October 6, 1864, that: "the ambulance wagon meets the approbation of the Board as one presenting some decided advantages over that now in use. It is recommended further that at least two to a division be furnished, so that a fair trial can be made of such vehicles." A number of the old pattern ambulance wagons were thereupon altered according to the plans submitted by Assistant Surgeon B. Howard, U. S. A., at the Government repair shops at Washington. But it seems that after nine months' experience in the field these ambulance wagons failed to meet the expected advantages. In a letter dated Medical Director's Office, Headquarters Fifth Corps, June 29, 1865, Surgeon Charles Page, U. S. A., remarks: "There have been two of the ambulance wagons in each division train of the corps, and for ease to the patient the report is universal in their favor. They are apt to get out of order, and being heavy cannot be carried where the other ambulance wagons can go. For marches I think the Howard ambulance wagon is superior; but for field work, in time of action, I would prefer the present Rucker pattern of ambulance wagon." In a reply to a note of enquiry from the Surgeon General dated June 29, 1865, Surgeon T. R. Spencer, U. S. V., from Headquarters of the Fifth Army Corps, takes a similar view: "So far as I can learn in this corps, it is not regarded as an improvement upon the old one. It is so heavy as to require four horses, else it rapidly destroys two. It is so complicated as to be continually getting out of order. As now constructed the ambulance wagon does not ride as easy over all roads as the old one. The only advantage it seems to possess is in the greater convenience of loading and unloading; this soon results in the loss of the bed, as officers will not consent to be removed from the bed during transportation. Once lost, or taken from the ambulance wagon, the bed is never returned, and the wagon is henceforth useless."

In the winter of 1864–'65 an ambulance wagon, proposed by Dr. I. Langer, was used at the Fifth Army Corps Depot Hospital before Petersburg. It was arranged to accommodate eight persons, four in sitting and four in recumbent positions, or six in sitting

and two in recumbent, or all eight in sitting postures. The advantages claimed were, greater seating capacity, greater facilities for loading and unloading, greater comfort to patients, offering easier access to each single patient, superior ventilation, and that it had apparatus for suspending two patients with compound fractures of the thigh. In April, 1865, a Board was convened, consisting of Colonel R. O. Abbott and Assistant Surgeons

FIG. 473.—An army wagon fitted up as an ambulance wagon. [After LANGER.]

J. J. Woodward and William Thomson, U. S. A., to examine and report on this ambulance wagon. The Board considered seriatim the advantages claimed by Dr. Langer, basing its opinions on comparisons with the Wheeling and the Rucker patterns then most generally in use: "The model examined is altered from a Wheeling ambulance wagon; the changes are radical and the additions numerous. So ingeniously complicated are the appliances, and so multitudinous the objects to be obtained, that the wagon would fail to meet the test of field service. The probable loss of its numerous detached pieces would rob it of all its special advantages, and leave it less useful than the Wheeling and Rucker wagons. In comparison with the former it has some advantages; but it fails to compete in practical usefulness with the ambulance wagon devised by Brigadier General Rucker." With regard to the apparatus for the purpose of transporting two thigh fractures the Board find: "The novelty of the method and the uncertainty of its practical value would not warrant the alteration of all the ambulance wagons in the service to fit them for transporting in this manner an occasional fractured femur." The Board refused to recommend the introduction of the Langer ambulance wagon into the service in preference to those then in use. At the same time Dr.

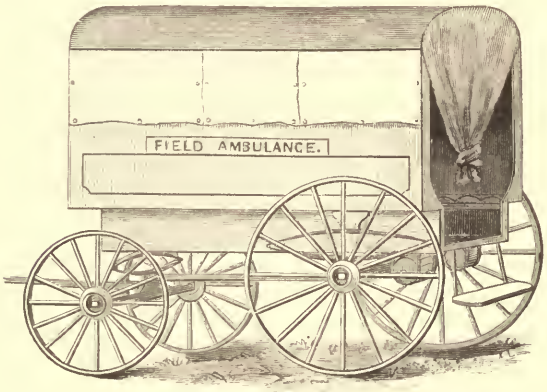

FIG. 474.—The Confederate field ambulance wagon. [After CHISOLM.]

Langer submitted to the Surgeon General for inspection an army wagon (FIG. 473) which had been fitted up with twelve beds for transporting patients. Dr. Langer claimed "that this change of the army wagon would not interfere with its design of conveying forage or other articles to and from a camp; that when the wagon is used for carrying forage the twelve beds are packed under a movable bottom, and the railing supporting them is stowed away on the sides, so that the capacity of the wagon box is not impaired; that in ten minutes after the wagon is unloaded it is changed into an ambulance wagon with all the equipments for transport—six patients in a sitting posture, six in a lying, two of which, if necessary, suspended on fracture beds of Dr. Langer's pattern; that there is room for all the equipments of the patients, for a water-keg, and for boxes with provisions and bandages, and that the wagon can be loaded from the front as well as the rear." As far as can be ascertained the experiment was tried but once. A drawing of the Confederate field ambulance wagon is copied from Chisolm[1] in FIG. 474. No description of the vehicle could be obtained.

RAILWAY TRANSPORTATION.

The facilities afforded by railroads for the movement of troops and material to the theatre of warfare have formidably augmented the destructive power of armies; but they have also offered useful and most effective means of saving lives and alleviating suffering by the speedy removal of the sick and wounded from the scene of active operations. After the battle of Gettysburg, in July, 1863, for instance, twenty thousand three hundred and forty-two wounded came under the care of the medical officers of the Army of the Potomac, and in two weeks fifteen thousand four hundred and twenty-five had been forwarded to Baltimore, York, Harrisburg, and New York City. Of the remainder a large proportion was unable to bear the fatigues of a protracted journey. After the bloody battles of the Wilderness and Spottsylvania the distribution of the wounded was even more rapidly effected, and, with a few exceptions, the fallen were, within a few days, comfortably sheltered in the hospitals at Alexandria, Washington, Baltimore, Philadelphia, and New York.

By rapid dispersion of the disabled the fighting force is less diminished than by any other plan. Fewer combatants are withdrawn from their proper duties to attend their sick and wounded comrades. With proper inspection of those sent to the rear, and such enforcement of discipline in the base hospitals as will ensure the prompt return of convalescents, the number of sick and wounded engaging in fresh active service will be greater than by any other arrangement; and a less proportion of division, brigade, and regimental medical officers and hospital attendants need be detached from the marching columns, which, in the exigencies of actual battle, are rarely adequately supplied with surgical assistance. Large accumulations of medical and hospital supplies with the army become superfluous. The depot hospitals, frequently great lurking places for malingerers, may be reduced to the smallest compass. If, without changes, the wounded can be directly placed in a fixed hospital not too distant, many primary mutilations may be justifiably avoided, with a view of employing more delicate special operations when the patients arrive at a safe place of rest. Lastly, the most important consideration is the most obvious, the distribution of the sick and wounded prevents the generation of those pestilences that are the greatest scourge of armies. The sick and wounded avoid infecting each other, and those who are well escape contagion.

In a report published from this office[2] on the subject of transportation of wounded by

[1] CHISOLM (J. J.), *A Manual of Military Surgery*, Columbia, 1864. PLATE I.

[2] OTIS (GEORGE A.), *A Report on a Plan for Transporting Wounded Soldiers by Railway in Time of War*, Washington, War Department, Surgeon General's Office, 1875.

railway, the means employed have been considered at length, and as there is very little to be added to that report, it is deemed best to reproduce such portions of the report as refer to railway transportation during the late war:

"After the action at Wilson's Creek and minor engagements in central Missouri, in August, 1861, the severely wounded fell into the hands of the enemy. They were soon paroled and concentrated at Rolla, the southwestern terminus of the St. Louis railroad, whither two hundred less grievously injured, and carried off by the retreating army, had previously been sent. Here, the freight cars available were fitted up for the transportation of this large body of wounded to the hospitals established at St. Louis. Various expedients were employed to adapt the cars to the requirements of the different classes of patients. * * * Seasoned tent-poles were shaved down to give them as much elasticity as was compatible with requisite strength, and secured transversely near the roof, passing through holes in the side studs of the car. Ropes attached to these poles and also to the floor suspended two tiers of field stretchers, on which pallets were laid. With this plan a feeling of insecurity was common to the patients and attendants, and additional lashings and constant inspections were necessary to prevent accidents. Another method consisted in placing a double row of upright stanchions, which were erected on either side of the car (FIG. 475), connecting the floor and roof, at intervals of seven feet lengthwise. To these firm posts tiers of two or three litters were securely lashed. In other cars rough wooden bunks were built along the sides of the vehicle and filled with straw, and made more comfortable by being floored by narrow elastic slats. In all cases large window spaces were sawn out of the ends and sides of the car to afford ventilation. There was often cause to remark on the great ingenuity displayed, on this and other similar occasions, by the line officers, quartermaster's men, and the soldiers themselves, in improvising various contrivances for the comfort of the wounded subjected to these rough modes of transportation. With an intelligent adaptation of the means at hand it was found practicable to make the condition of the wounded on freight cars very tolerable with the aid of articles belonging to the field equipment alone. * * *

FIG. 475.—Interior of an improvised hospital car.

"After the Army of the Potomac left the vicinity of Washington the sick and wounded were removed mainly by the hospital transport steamers on the Potomac, Rappahannock, York, and James rivers. The short lines from Savage's Station to White House, on the York, and from Aquia Creek to Fredericksburg, were largely utilized, however, for the same purpose; and when the theatre of hostilities was transferred to Maryland and Pennsylvania numerous railway lines became available. Medical Director J. Letterman recorded the transfer[1] of no less than nine thousand sick and wounded over the Aquia Creek road on June 12th, 13th, and 14th, 1863, when the army moved northward after the disasters of Chancellorsville. All patients that would be injured by sitting up were carried by hand to the railway on the beds they occupied in hospital, the beds being placed on hay-covered floors in freight cars.

"The following year, when this army was massed before the entrenched line at Petersburg, a large depot hospital was erected at City Point, the base of supplies, at the junction of the James and Appomattox rivers. This depot was connected with the positions of the several army corps by a railroad with branches, and the sick and wounded from the division hospitals were brought to the depot chiefly in the box-cars which had carried forward supplies for the troops, and were transferred to hospital steamers, or retained at City Point for treatment, at the discretion of the medical director for transportation, Surgeon E. B. Dalton, U. S. V. There were at first two, and, subsequently, a larger number of passenger cars converted into hospital cars by the erection of rows of stanchions, to which litters were suspended by elastic rubber rings, each car having accommodation for thirty recumbent patients. The box-cars, with door-ways at the sides 5 feet in width and an interior height in the centre of 6 feet 9 inches, had a floor space of 25 feet 2

[1] LETTERMAN (J.), *Medical Recollections of the Army of the Potomac*, New York, 1866, p. 150.

inches in length by 7 feet 8 inches in breadth, or about 192 square feet. They afforded comfortable accommodation for nine recumbent patients, but were sometimes packed with as many as twenty. When the floors were covered with a thick bed of fresh straw or hay, on which well-filled bed-sacks or mattresses could be laid, the concussions from the motion of these rough cars were so much deadened as not to be intolerable even to severely wounded men. There was a great advantage in carrying the wounded on the beds or litters on which they lay through the wide doorways of the box-cars, and unloading them, in like manner, at the depot hospital or the wharves of the transport steamers at City Point. It was, however, very difficult to obtain an adequate supply of straw or hay when, after a general engagement, train after train was sent in rapid succession, and recourse was sometimes had to bedding of dry leaves or evergreen boughs. In one of the reports to Medical Director T. A. McParlin[1] it is stated that it was necessary to empty the bed-sacks of the field hospitals of a corps in order to obtain sufficient bedding for the box-cars of a train of wounded.

"In the summer and autumn of 1862, and during the two succeeding seasons, four large brigades stationed at New Berne suffered from malarial fever to that extent that general hospitals, or rather *sanitaria*, of great capacity, were established on the sea-coast at Carolina City, near Fort Macon, the former connected with New Berne by a railway forty miles long. The patients were conveyed in freight cars, for there were no others available. The floors of the cars were covered with dry 'pine tags' supplemented by a layer of loose hay or straw when it could be procured. The patients were laid upon bed-sacks on this substratum, and even those most gravely ill were transported with comparative comfort. Medical Inspector E. P. Vollum, U. S. A., has recorded[2] that after the battle of Gettysburg, July 1–3, 1863, over fifteen thousand wounded were sent from the field hospitals prior to July 22d, nearly all by railway to Baltimore, York, Harrisburg, and Philadelphia. They were transported, in large proportion, in the box-cars of the returning supply trains. 'Each car was supplied with a sufficient quantity of hay, and, on the longer routes, water-coolers, tin cups, bed-pans, and urinals were placed on them.' After the battle of Olustee, February 20, 1864, where the wounded of the Union side numbered over eleven hundred, Assistant Surgeon John H. Janeway, U. S. A., states that the grave cases of compound fracture and of penetrating wounds of cavities, and, indeed, all the more seriously wounded, were transported on the Mobile Railway on freight cars bedded with pine boughs, palmetto leaves, and a small allowance of straw, covered with blankets. The trains moved slowly from Sanderson to Jacksonville, on the coast, a distance of nearly fifty miles, and patients who had undergone amputation, and others severely wounded, complained but little of the rough method of transit. In the campaigns about Chattanooga, also, Medical Director G. E. Cooper, U. S. A., reported that in emergencies, when the regular hospital trains were overcrowded, recourse was often had to transport by freight cars bedded with dry leaves.

"In a letter to the Surgeon General, dated Philadelphia, January 7, 1863, Surgeon A. K. Smith, U. S. A., describes 'a car recently fitted up by the Philadelphia Railroad Company for the better conveyance of the worse class of sick and wounded. * * * The internal arrangements are similar to those of sleeping cars, with the exception that the berths slide in and out, and two men can carry each, with its patient, to the ambulance wagon or the nearest hospital, the berths being, in fact, comfortable stretchers. The car has fifty-one of these berths, and a seat at each end for an attendant. It is provided with a stove, on which soups can be cooked, a water-tank and locker, and a convenient water-closet. It is proposed to use the car with the regular passenger trains, and to bring to Philadelphia cases of a more serious nature than can be selected for transfer by the ordinary mode of travel. This arrangement is entered into with great zeal by Mr. Felton, president of the road, the plan being in a great measure due to the efforts of Mr. William Welsh. If proved to work well, I am satisfied in saying that more cars will be similarly constructed for the purpose of bringing the seriously sick and badly wounded from Frederick and Harper's Ferry.' This proposition was warmly seconded at Washington, and a number of passenger cars, converted to hospital requirements, and hospital cars also of special construction, were soon in operation on the railway lines connecting the theatre of hostilities with Baltimore, Harrisburg, Philadelphia, and New York. They were not fitted up on a uniform plan, but under the auspices of different

[1] A Report from the Fifth Corps headquarters by Assistant Surgeon C. K. WINNE, U. S. A.

[2] VOLLUM (E. P.), *Report on the Transportation of the Wounded after the Battle of Gettysburg*; in *Appendix to Part I, Medical and Surgical History of the War of the Rebellion*, Washington, 1870, p. 143.

benevolent associations; but all secured a comparatively comfortable mode of transport for recumbent patients, and rendered almost inestimable service in relieving the crowded hospitals near the scene of hostilities. The hospital cars fitted out by the United States Sanitary Commission are understood to have been arranged in accordance with plans furnished by Dr. Elisha Harris.[1] A model of one of these cars was exhibited at the Paris Exposition of 1867 (see FIG. 476). These cars were about fifty feet in length. A passage-way extended through the middle to the doors at either

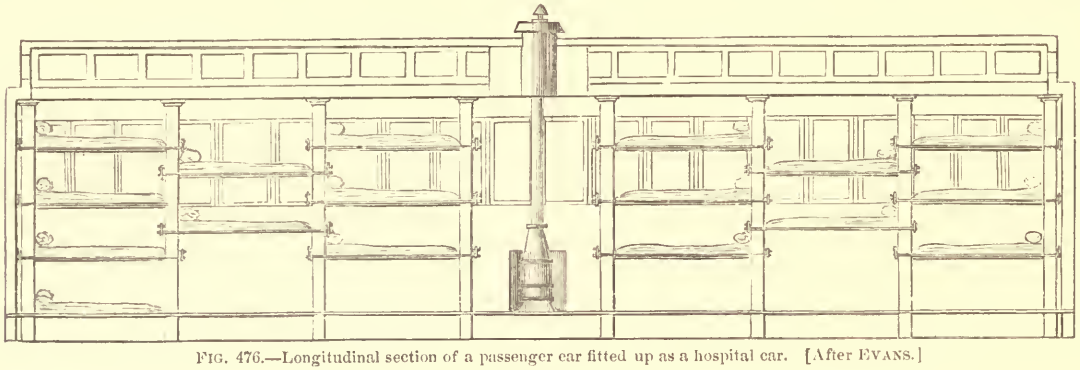

FIG. 476.—Longitudinal section of a passenger car fitted up as a hospital car. [After EVANS.]

end. On either side of the passage-way were eight upright wooden posts, three inches square, connecting the floor and ceiling, and so placed that the distances apart should correspond with the length of a field stretcher. At a distance somewhat less than the width of a field stretcher, opposite each pillar, another post of like dimensions was placed next the side of the car; thus one side-pole of a stretcher was attached inside the wall-pillar and outside the pillar next the passage-way, and its suspension was rendered easier than if it was confined between the rigid pillars. Wooden pegs inserted in the posts served for the attachment of large rubber rings (FIG. 477), which received and sustained the ends of the stretcher poles. Thirty-two litters could be suspended, leaving a space in the middle for a stove and seats for attendants or wounded who could travel in a sitting posture. It is stated[2] that some of the india-rubber rings that had been in use in these cars were exhibited in Paris in 1867, and were still in perfect order. I have been informed that these cars had doors of three feet in width; but even this space would be insufficient, if the litters were as wide as represented by Dr. Evans. The ordinary field stretchers used in the United States were uniformly 24 inches wide, and it was this form of stretcher that was generally employed upon the hospital trains. Although the advantage of caoutchouc rings for the suspension of litters was generally conceded, and the inventor and exhibitor were rewarded with medals, many objections were raised to the arrangements of the car exhibited in Paris. Dr. Lœffler[3] declared that the inconveniences attending the transport of wounded in tiers of three superimposed berths were so considerable that the project must be abandoned. Professor Gurlt[4] referred to the danger of 'the frequent jolting of the car, striking the poles of the stretchers against the posts and communicating concussions to the litters and the patients, which may have the gravest consequences for the latter.' Professor Billroth[5] objects to these and all other arrangements for the railway transport of wounded that cannot be extemporized.

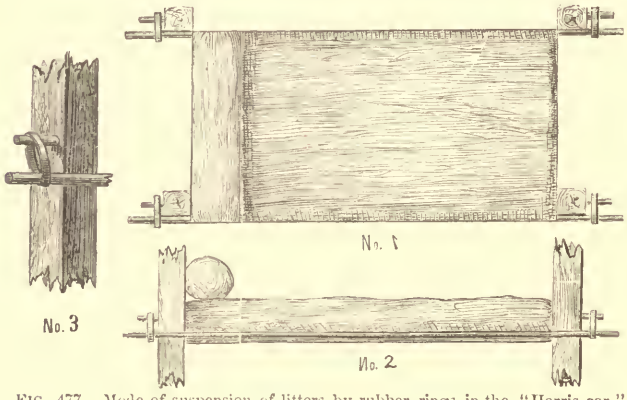

FIG. 477.—Mode of suspension of litters by rubber rings in the "Harris car." 1. Vertical view; 2. Lateral view; 3. Enlarged view of one of the rings. [After EVANS.]

"When the Army of the Potomac advanced to the line of the Rapidan, the Medical Director of the Department of Washington, Surgeon Robert O. Abbott, U. S. A., recommended that an hospital train of twelve cars, one fitted up as a dispensary and store-room for supplies, one for the surgeon in charge and attendants, and ten for the sick and wounded, should be constructed on plans and specifications prepared by the Assistant Superintendant of Military Railroads, J. McCrickett,[1] remarking that 'during the past year two or three cars somewhat similarly fitted up, provided with medical officers, nurses, and the proper medical appliances, have been running, under my direction, between this city, Philadelphia, and New York, and I make this request upon my experience of their practical working and the satisfaction they have given to patients, their friends, and this office. At present, the sick and wounded are transported in cars illy adapted for the purpose, and with difficulty spared from the other pressing demands, and lives are lost on the route, not infrequently, which in all probability might be saved by a more comfortable and easy method of transportation. These considerations and the extended facilities such cars will give for transportation of the wounded particularly, will, in my opinion, justify the expense of construction.' It was designed that this hospital train should ply between the advance of the army, near Culpeper, and the base hospitals at Alexandria and Washington, and should supplement or supersede the freight cars bedded with straw or hay that had been hitherto in use. The Surgeon General and Quartermaster General cordially endorsed this project, and several complete hospital trains were soon in operation on this line.

FIG. 478.—Transverse section of hospital car on the Orange and Alexandria railroad.

"FIGURE 478 is a reduction from Mr. McCrickett's 'end elevation of the hospital car, showing the litters in place, and the mode of hanging them. The bottoms of the permanent couches, two and a half feet wide, are made either of wooden slats or of canvas, with mattresses laid upon them. For the second and third tiers, ordinary field stretchers are used. The inside poles of the litters are suspended by a leathern strap or by strong webbing, the strap secured to a carling of extra strength; the outside handles of the litters are supported by hooks of spring steel. There should be some space between the inside litter handles and the side of the car to prevent concussions;

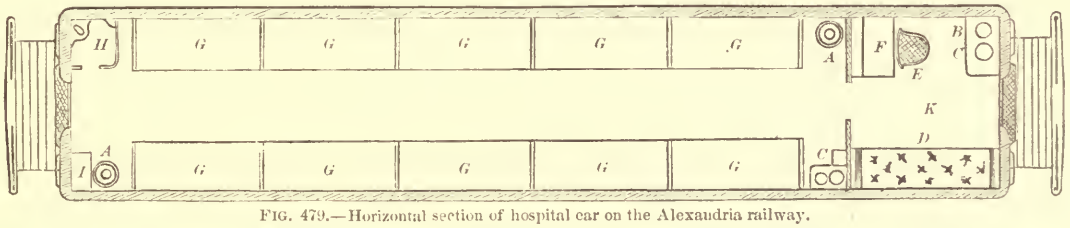

FIG. 479.—Horizontal section of hospital car on the Alexandria railway.

A—Stoves. C—Wash Basin. E—Chair. G—Tiers of couches. I—Wood Box.
B—Water-cooler. D—Lounge or couch. F—Table. H—Water-closet. K—Surgeon's office.

the hooks so constructed as to act as springs. The litters of the second and third tiers, when not in use, can be taken down and folded under the permanent couches. The straps also can be taken down or rolled up; there will then be no obstacles in the way when loading the cars with patients.

A door three feet and a half wide, *at one end*,[2] gives ample room for ingress and egress of loaded stretchers. The aisle is three feet and a half wide and can be occupied by folding chairs for those who can travel in a sitting posture, the chairs being stored under the permanent couches. The

[1] Mr. J. McCRICKETT estimated that the twelve cars could be built in thirty days, at an expense not exceeding $30,000, if the task of construction was divided among the factories at Wilmington, York, Harrisburg, Philadelphia, and Springfield, Massachusetts. He thought it "much better in many respects to have the cars made to order than to buy them at second-hand and have them altered," since railroad companies "can ill spare any of their rolling stock at this season, and would sell only worn-out or condemned cars, the alteration and fitting up and repairs of which, added to the prime cost, would demand a greater sum than would be required for new hospital cars." It is impracticable to ascertain from the records of the Bureau of Construction of Military Railways whether a full train was built in accordance with the plans and specifications of Mr. McCRICKETT, prepared in consultation with Surgeon E. BENTLEY, U. S. V. It is known that the construction of a number of hospital cars was authorized about this time, at different car-shops, and that several hospital trains were soon in operation on the Orange and Alexandria line; but they were not of uniform patterns. In many of them, the litters were suspended by india-rubber rings. It is probable that the cars constructed under the direction of the Sanitary Commission and those built by Government order would often be connected or separated on the different lines as the exigencies of the service required.

[2] At the other end, represented in the elevation (FIG. 478), the door opening into the attendant's room is only two feet wide.

capacity of the car, which measures inside eight and a half feet in width, forty-five and a half feet in length, and six feet eight inches in height, permits the transportation of fifty or sixty patients—thirty in couches and the others in chairs.' FIGURES 479 and 480 explain themselves.

"With the addition of special cars fitted up with rooms for kitchens, dispensaries, store closets, quarters for the employés of the train, offices for the executive officer, etc., a well-organized railway ambulance train became a nearly complete movable hospital establishment, with every reasonable appliance for the sustenance, dressing, nursing, and medication of the patients. The hospital trains of the armies in the East traversed railways within the Union lines, and were seldom molested. They were moved generally at a low rate of speed. They were distinguished by displaying the yellow hospital flag near the engine, and by the inscription 'U. S. Hospital Train' painted in large letters on the panels of the cars.

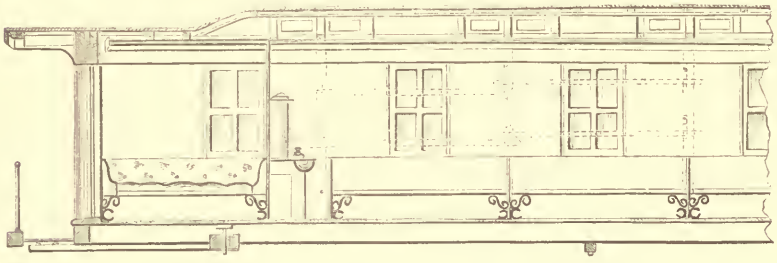

FIG. 480.—Lateral elevation of a part of one of the cars on the Alexandria line.

"The hospital cars prepared under the supervision of the Government officials and those arranged under the direction of the agents of the Sanitary Commission were usually passenger cars converted to hospital use, although the kitchen and executive cars, and a few of those for the conveyance of the sick and wounded, were built specially for the purposes they were designed to subserve. There was great variety in the details of the internal arrangements; but nearly all conformed to the general plan of securing berths in tiers to rows of uprights. The cars constructed by different builders varied in dimensions. The longest were 58 feet in length including the platforms. The usual interior length was 45 to 50 feet, which afforded space for five or six sections of stretchers on each side, and space for stoves, lavatories, water-closets, and seats for attendants. The height at the sides was 6½ feet, the roof sloping upward to 7½ feet, and being surmounted by a clear story of 2 feet provided with windows and ventilators.

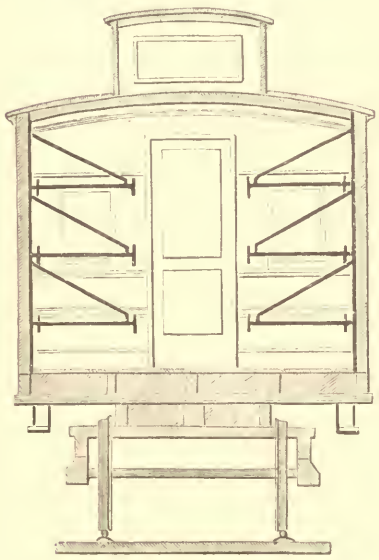

FIG. 481.—Transverse section of a passenger car fitted out by Acting Assistant Surgeon J. P. Barnum, and known as the "HARRIS Car."

"It was in General George H. Thomas's Army of the Cumberland, of which Surgeon George E. Cooper, U. S. A., was Medical Director, its long line of communication extending hundreds of miles away to its base of supplies, that the utility of railway transport, in relieving the army of its disabled men, was most conspicuous. Although freight cars were used for very severe cases, several trains of hospital cars of special construction were prepared at the Government work-shops for the conveyance of patients in the recumbent posture. In 1864 there were three hospital railway trains, each consisting of ten or twelve cars, with several freight or baggage cars attached sometimes, connecting the advance of the army with Nashville and Louisville; one train, at least, daily leaving the vicinity of the field hospitals. In each train one car was fitted up exclusively as a kitchen and store-room, and another as a dispensary, with accommodation for the medical officer in charge, and an ample supply of medicines, stores, instruments, and appliances. Surgeon Cooper reported that upon his arrival in the Department a train of passenger cars fitted up for the transport of sick and wounded by Acting Assistant Surgeon J. P. Barnum was already in operation on the line, a hundred and eighty-five miles in length, between Louisville and Nashville. This train had been prepared at Nashville under the direction of the Western Sanitary Commission. Each of the cars accommodated thirty-three recumbent patients. The pallets were placed in tiers of three, supported by iron brackets attached to the sides of the car, and swung on india-rubber springs (FIG. 481). 'The bed-frames,' Surgeon Cooper remarks, 'resemble stretchers with a portion of the handles sawn off. This style of car is objection-

able on account of the surgeon being unable to manipulate the wounds, when they require dressing, without great inconvenience to himself. The space between the beds is too contracted, and causes much complaint from the wounded. There is too much motion in the beds, and altogether the car is not a good one.' Dr. Barnum states that during his connection with the railway hospital service he 'supervised the transportation of 20,472 patients and lost but one, who, despite the advice of his surgeons, implored that he might be taken to die in the bosom of his family.'[1]

"The cars thus arranged, and others in which litters were suspended by india-rubber rings from pegs inserted in upright posts, as in the Eastern hospital trains, were alike known at the West, under the designation of the 'Harris car.' Dr. F. L. Town, U. S. A., in a report to Assistant Surgeon General R. C. Wood, refers to them as follows: 'Other ways of securing the beds have been tried. The 'Harris car' is in use, with beds arranged in three tiers, each bed resting on stretchers, suspended by four rubber rings, between uprights. Each rubber ring encircles a pin in the upright

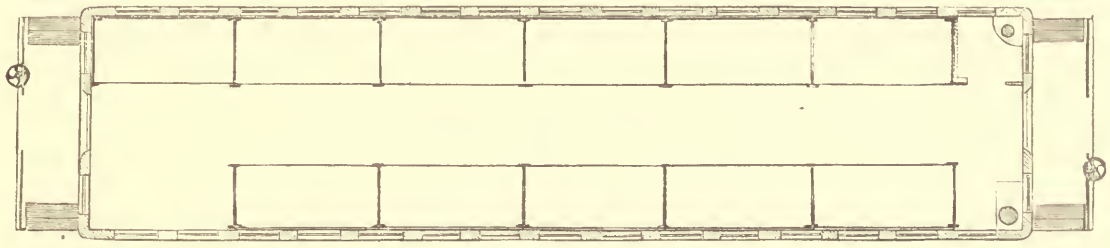

FIG. 482.—Reduced plan of a horizontal section of one of the cars of Dr. Barnum's train, showing the positions of thirty-three litters, the wash-room, and water-closet. [From a drawing furnished by Medical Director COOPER.]

and holds up one end of the lateral bar of the stretcher. This arrangement has one advantage—the stretcher can be unshipped, and, if necessary, the occupant can be borne away without disturbing him. A ward in the 'Harris car' contains thirty-three or thirty-six beds. The removal of one section of the tiers, that is, three litters, affords room for a stove in cold weather. The 'Harris car' has not worked well in practice. The elasticity of the rubber bands keeps the bed in constant vibration while the car is in motion, to the great annoyance of the patients, who complain of reclining on what they term 'a capering bed.' Severe cases are now conveyed in the cars to be hereafter described.

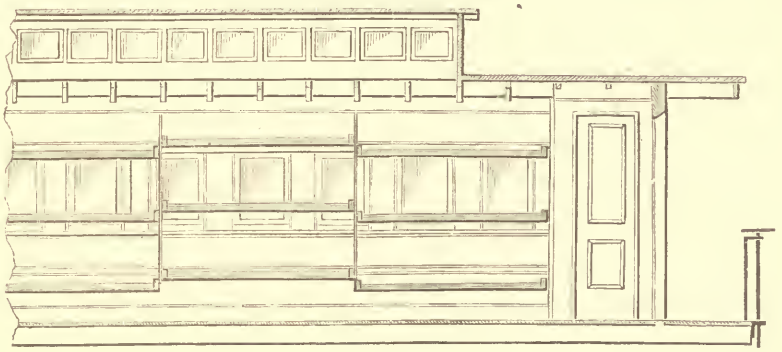

FIG. 483.—Lateral view of half of a hospital car of Dr. Barnum's train, showing the arrangement of the litters and the wide side door. [From a drawing from Dr. COOPER.]

"FIGURES 482 and 483 further illustrate, by horizontal and lateral views, the arrangement of one of the hospital cars of Dr. Barnum's train. They are reductions from drawings prepared for Dr. Cooper by a draughtsman of the Nashville Car Manufactury. Some further particulars respecting the method of suspending litters by rubber tugs or rings, and the means of obviating the excessive oscillation often complained of as a grave objection to this system, will be noticed further on.

"Medical Director George E. Cooper preferred the arrangement of the ordinary first-class passenger cars on the plan indicated in FIG. 484. The cars of this class were usually fifty-five feet long and nine feet four inches wide, with a doorway twenty-two inches wide at either end, a passage way of equal width through the middle, and, on either side, a row of fourteen double seats. Dr. Cooper describes the arrangement (FIGS. 479, 480) he commends as follows: 'The cars thus prepared have a capacity for thirty-three patients. The beds are made by removing the alternate seats, and connecting the remaining seats with slats of ash or some other springy wood. Two bed-sacks are laid on the slats. The wounded are carried on the slats covered with bed-sacks, and are placed

[1] EVANS (T. W.), *La Commission Sanitaire des États Unis*, Paris, 1865, p. 135. Medical Director COOPER doubts this remarkable immunity from deaths in transit on the hospital trains directed by Dr. BARNUM, while testifying to the indefatigable zeal and efficiency of the latter during his protracted service. "Acting Assistant Surgeon J. P. BARNUM," remarks Dr. TOWN, "had charge of the first hospital train built at Nashville. He studiously labored to improve and systematize its working, and devised many expedients looking to the comfort of the patients in days when the theory of hospital trains was not so well understood as now."

two on each bed. The upper beds are framed as stretchers, and are hooked to the side and ceiling of the car and covered with a mattress. On this upper tier the less gravely wounded are carried. This plan was found to be the best, the least expensive, and the most comfortable to the patients of all the hospital cars in use. The medical attendants could dress wounds in these cars without much inconvenience.' On the drawings sent with this description Surgeon Cooper annotates: 'This is the simplest and best form.'

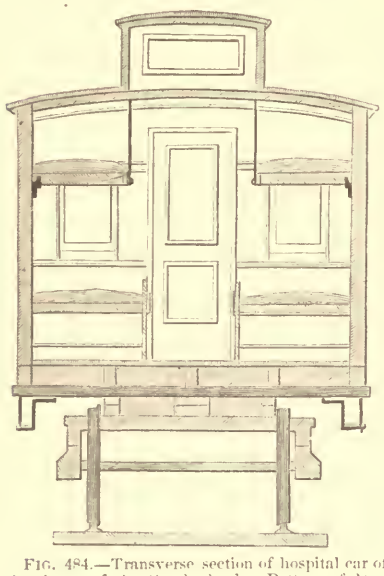

FIG. 484.—Transverse section of hospital car of the Army of the Cumberland. Pattern of Drs. Cooper and Herrick.

"Dr. F. L. Town, U. S. A., gives the following description of five of these cars which he inspected: 'Each ward contains about twenty-four beds, arranged lengthwise along either side of the car, in two tiers; the upper bed exactly above the lower. In the lower tiers the bed is fixed firmly upon the car-seats; the backs of these [and an intervening seat] are removed. Its width is that of the car-seat [about forty-four inches], and its distance from other beds is the space between adjacent seats. In the upper tier the beds are about two-thirds as wide, and are on stretcher-frames, attached firmly on the outer side to the wall of the car, and suspended on the inside by two iron bars from the roof. Each upper bed thus stands or hangs immovably in its place. The wide beds in the lower tier are considered double, and, on short routes, are often occupied by two patients regarded as mild cases. The American railway companies appreciate economy of space in their sleeping cars, and the plan of transporting two persons in one bed is not claimed as original in hospital trains. The hospital car is supported on trucks with elliptical steel springs, as is usual in passenger cars, and, in addition, india-rubber springs are so arranged as to equalize the motion and deaden the jarring of the car. This is a very valuable improvement and adds much to the comfort of the patients. In the wards above described the patients ride with much ease and every possible provision for their comfort.' FIG. 485 shows the horizontal plan of one of these cars.

"These cars were fitted up under the immediate supervision of Medical Director Cooper and of Surgeon O. O. Herrick, 34th Illinois Volunteers. The latter was at one time in charge of one of the trains, and is officially reported as having rendered signal service in devising expedients for

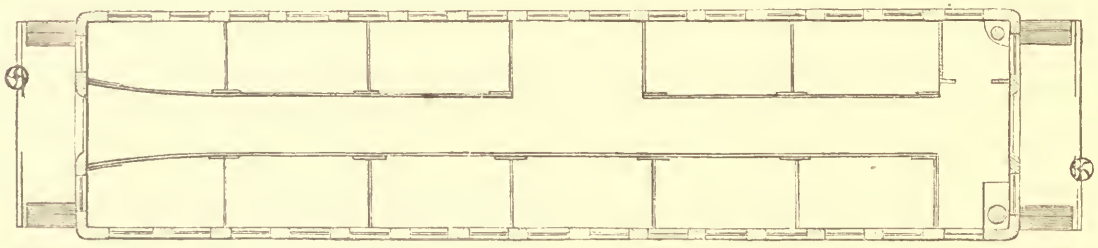

FIG. 485.—Horizontal plan of one of the hospital cars of the Army of the Cumberland.

facilitating the safe transport of wounded and in promoting the organization and administration of the system. General Thomas accorded the fullest authority to Medical Director Cooper to select for the hospital trains the best locomotives and cars to be found among the rolling stock, and to have new cars fitted up whenever necessary, and caused to be detailed for the hospital service the most experienced conductors, engineers, and other employés of the several railway lines. Medical Director Cooper informs the reporter that the smoke-pipes of the locomotives of the hospital trains were painted of a brilliant scarlet; the exterior of the hood, and of the tender car with water and fuel, were of the same conspicuous color, with gilt ornamentation. At night, beneath the head-light of the engine, three red lanterns were suspended in a row. These distinguishing signals were recognized by the Confederates, and the trains were never fired upon or molested in any way. Dr. Cooper 'was informed by wounded Confederate officers in Nashville, who were captured at the battle near that place, of the stringent orders given his troopers by General N. B. Forrest for the non-interference with and protection of the U. S. A. hospital trains,' by giving

them timely warning in the event of the railway being obstructed or torn up. The partisan troops of Colonel John Morgan's command had similar instructions. It is related that on one occasion Colonel Morgan's scouts stopped the train directed by Dr. Barnum, and having switched it off upon a siding, after inquiring if there were sufficient stores on the train for the sick and wounded, they tore up the main track, and then rifled and destroyed five supply trains that successively arrived at the point where the line was interrupted.

"Ventilation without exposure to drafts was well provided for in these cars by windows in the elevated part of the ceiling and by valvular openings near the roof (FIG. 486). Dr. Town comments on the admirable manner in which the apparatus for lighting and heating were made also to promote ventilation. He refers to many other details, which there is not space to notice here, and concludes that 'the conception of a complete hospital, with all its appliances and means of comfort, propelled by steam, was first carried into practical operation in the medical department of the West, and its perfect success was most gratifying to all. In visiting these hospital trains, the air is found sweet and pure, the wards neat and inviting, and it may unhesitatingly be said that men on hospital trains are often as comfortable, and better fed and attended than in many permanent hospitals.' Besides Drs. Barnum and Herrick, Medical Director Cooper mentions Surgeon L. J. Dixon, 1st Wisconsin Volunteers, and Assistant Surgeon E. J. Darken, U. S. A., as having supervised hospital trains with great skill and devotedness. Of the Medical Director himself, Dr. Town observes: 'Colonel George E. Cooper has made the study of hospital railway trains his pride. All of the western trains have been in the Department in which he directs the medical service, and many of the cars have been fitted up under his supervision. * * * He has just cause to be proud of his hospital trains.' As far as the records of the Assistant Surgeon General's Office show, the first official step toward organizing hospital cars was a letter written August 11, 1863, from that Office by Surgeon Joseph P. Brown, U. S. A. (during the temporary absence of the Assistant Surgeon General on other duty), directing the Medical Director of the Army of the Cumberland 'to take immediate measures to fit up a special train for hospital purposes, with every possible comfort,' to run between Nashville and Louisville.

"When General Sherman's army was before Atlanta, until the lines of communication were destroyed preparatory to the march to the sea, hospital cars ran regularly from the front to base hospitals, some of which were four hundred and seventy-two miles distant.[1]

"The difficulty of introducing loaded stretchers or litters through the narrow end doors of the converted passenger cars was obviated, in the train prepared under the supervision of Drs. Cooper and Herrick, by leaving the middle section on one side free from beds, removing two windows and the paneling beneath, and introducing a sliding door, six feet in width, affording an ample space for the ingress and egress of litters with the most severely wounded patients. Descrip-

[1] Surgeon F. L. TOWN'S report.

tions of the kitchen, office, and dispensary cars, which added greatly to the efficiency of these trains, are omitted here. A further description of the hospital trains of the Army of the Cumberland has been given by Dr. Dallas Bache, U. S. A.[1] In addition to the illustrations that were published with his paper, it may be useful to add diagrams explaining the details of the arrangements for suspending litters from upright posts in adapting cars for hospital purposes (FIGS. 487, 488, 489) that were planned by Dr. Harris in December, 1862, and successfully put in practical operation in the Spring of 1863. It has already been shown that the adaptation of cars to hospital purposes by securing field stretchers to rows of stanchions was practised from a very early period of the late war; but the merit of devising a simple and effective method of suspending the stretchers by rubber rings was exclusively due to Dr. Elisha Harris, who, moreover, promoted with great earnestness, during the war, the establishment and organization of railway transport for the sick and wounded. A brief and somewhat inaccurate account of this system was published in 1865 by Professor F. H. Hamilton.[2] The plan was cursorily alluded to the same year in a surgical report from this Office,[3] and more fully described in a work by Dr. T. W. Evans, of Paris.[4]

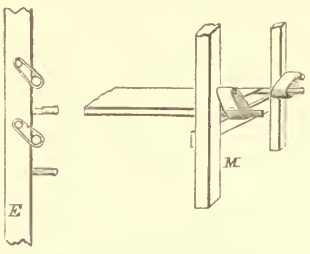

FIG. 488.—The "free" or inside method of suspending litters by rubber rings. [After HARRIS.]

"Dr. Harris proposed to suspend three tiers of litters from upright oaken stanchions 4 inches wide by 2 inches thick, extending from the floor to the roof of the car, which gave a length of about 6 or 6½ feet (FIG. 487, B and C). The stanchions were placed in pairs, the fellow posts 22 inches apart, and 6½ feet distant from the next couple (FIG. 492). The stanchions at the end of each row of uprights were perforated to receive on the broad face three hickory pins an inch in diameter, and three on the narrow face; the other stanchions, each pair contributing to the support of two tiers of litters, were provided with twelve pins (FIG. 487, B, C), six termed holder or loop-pins, and six arresting pins or stops (FIG. 487, F, D), designed to prevent the undue descent of the litter. Around the pins on the broad face of the pillars were placed loops or tugs of vulcanized india-rubber 3 inches broad, ½ inch thick, with 4 inches aperture, and weighing 9½ ounces Troy. The handles of the stretchers, sawn off at 7½ inches from the margins of the canvas, were inserted in the rings, which were put upon the stretch by the weight of the patient. Too great oscillation was prevented by the stopping-pins or by substituting more massive rubber rings. The holder-pin for the lower stretcher was 9½ inches from the floor, the stop-pin three inches. The space between the upper and middle and the middle and lower stretchers was about 19 inches. The inside length of the cars fitted up varied from 41 to 47 feet, and would accommodate four or five tiers of litters on either side, with space reserved for seats, closets, and offices at the ends. The inside width of the cars was 8 or 8½ feet, and as the two series of berths occupied but 2 feet 4 inches on either side, a passage-way of 3 feet 4 or 10 inches was left in the middle. The end doors, usually opening 2 feet, were widened to 2½, or, in the best models, to 3 feet. Hair pillows (FIG. 489) were attached to head-boards of ½-inch light wood, and secured by straps to the litter poles. Dr. Harris proposed a modification of this plan, designed to afford greater elasticity to the litters for the transport of severe cases. The inner edges of the upright stanchions were placed 26 inches apart, and the handles of the litter were hung between the posts (FIG. 488, M); a wooden or iron traverse was substituted for the stop-pins, and the mode of insertion of the pins in the uprights was altered (FIG. 488, E); larger rubber rings, weighing 12 ounces, were used. On experiment this

[2] HAMILTON (F. H.), *A Treatise on Military Surgery and Hygiene*, New York, 1865, p. 168. The remarkable statement is made that: "The stretchers are suspended on loops made of *gutta-percha*," a singularly unsuitable material.

[3] Circular No. 6, S. G. O., Washington, 1865. *Reports on the Extent and Nature of the Materials available for the Preparation of a Medical and Surgical History of the Rebellion,—Surgical Report*, p. 81. Diagrams were given (FIGS. 88, 89, 90), from a photograph by Gardner, of the working drawings of the first hospital car exhibited by Dr. HARRIS in Washington in March, 1863. I found the photograph on file, but, at that time, could obtain no precise information of its origin.

[4] EVANS (T. W.), *La Commission Sanitaire des États-Unis, etc.*, Paris, 1865.

plan was found inferior to the first. Most of the cars were provided at one end with a wash-room and water-closet (FIG. 491), and at the other end with a couch and seats for attendants, a stove, and a small closet for a few essential medicines and dressings, and a copper boiler with an alcohol lamp. This brief statement of details applies to many of the long passenger cars fitted up for hospital purposes upon specifications supplied by Dr. Harris. This original design of Dr. Harris was

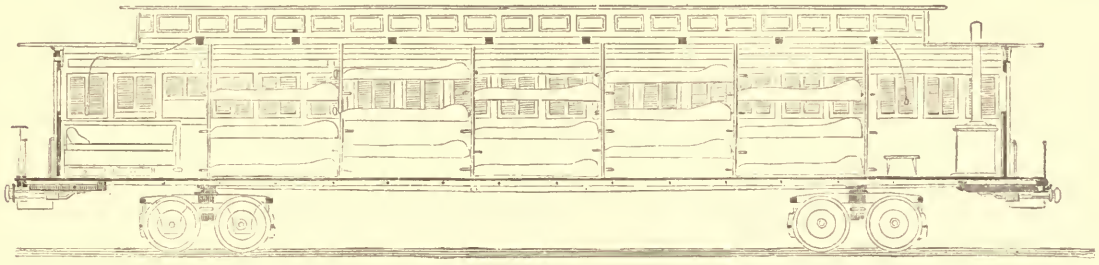

FIG. 491.—U. S. Army Hospital railway car used at the East—side elevation.

not, however, limited to transforming passenger cars to hospital use;[1] and the adaptation of elastic rubber rings[2] to the suspension of litters, though valuable, was not the most important and enduring part of his system. There will probably be many changes and improvements in the methods of moving wounded men by railway, but the idea of utilizing the ordinary field stretchers for railway transport, keeping the patients upon them until they reach a fixed hospital, will not soon be abandoned. This expedient had been already resorted to in isolated instances, but Dr. Harris proposed its systematic adoption and devised a feasible method for its accomplishment. The system was much commended in Europe.[3]

"At the close of the war there were in use thirty-nine cars that had been fitted out under the supervision of the Sanitary Commission. Except in a few instances, however, the Government had reimbursed the Commission for the original cost and the expenses of the outfit."

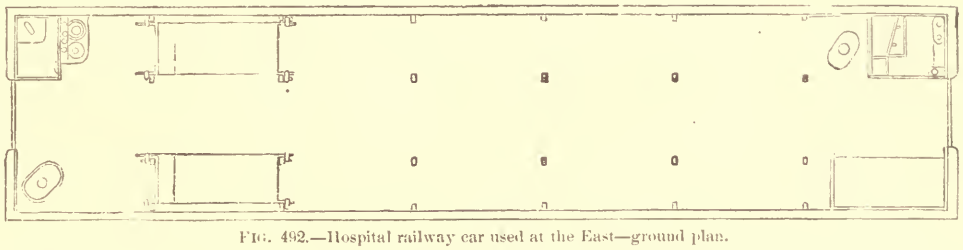

FIG. 492.—Hospital railway car used at the East—ground plan.

In the fall of 1863 and winter of 1864 the chief army of the West was concentrated[4] principally along the line of railroads leading from Nashville, Tennessee, southwest via Chattanooga, Tennessee, and stretching on toward Atlanta, Georgia. Heretofore such sick and wounded, on railroad lines, as could bear transportation were taken to points in the rear and north by ordinary passenger cars. Severe cases could not be removed at all and had to remain in the nearest hospital depots. Those *in transitu* often suffered from being delayed on the route by accident, or by the immense supply trains destined for the army constantly passing over the road. Not unfrequently the delay was at points where no rations could be drawn, and if they were to be had no means were at hand for cooking them, or feeding the men, or of making them comfortable. Hence the idea of a hospital train, an ambulating hospital, an independent hospital organization, which could furnish

[1] Dr. HARRIS wrote me, August 17, 1875: "The original sketch, made in June, 1862, is now before me, with the simple proposition: *To readily and securely suspend in any railway car* as large a number as possible of the field litters, as portable hammocks, to be passed onwards, as beds for patients, without delaying or encumbering transportation. The method of swinging in position and securely fastening the litters was settled in the first pencil-sketch; the details of a complete ambulance car were arranged the last week in December, 1862, and the first car fitted up, the pioneer, was the favorite old 51-feet car that was mutilated, when occupied by the 6th Massachusetts Volunteers, in the Baltimore riot of April, 1861."

[2] The elasticity of the rubber rings was objected to by some surgeons. Assistant Surgeon F. L. TOWN, U. S. A., remarks: "The Harris car does not work well in practice; the elasticity of the rubber rings keeps the bed in constant vibration while the car is in motion. This greatly annoys the patient, who objects to riding a capering bed."

[3] HAUROWITZ (H. v.), *Das Militärsanitätswesen*, 1866, S. 87.

[4] For the account of the management of the hospital trains of the Department of the Cumberland alluded to here, the editor is largely indebted to a manuscript report of Assistant Surgeon F. L. TOWN, U. S. A.

each sick and wounded patient with a comfortable bed, feed and care for him *en route*, the same as if in a general hospital, without regard to time or distance. Such hospital trains were in successful operation during the last eighteen months of the war.

A hospital train, when complete, is made up of ten cars, and accommodates from one hundred and seventy-five to two hundred patients comfortably. The arrangement of the train is as follows: One box car, one kitchen car, an ordinary passenger car with seats, five cars with beds, *i. e.*, hospital wards, an office car, and a conductor's car. The forward box car is fitted up as a storeroom and carries provisions, hospital stores, bedding, etc. The drawings and brief descriptions of this as well as of kitchen and surgeon's cars of the Army of the Cumberland

FIG. 493.—Baggage and commissary car of the Army of the Cumberland—horizontal plan.

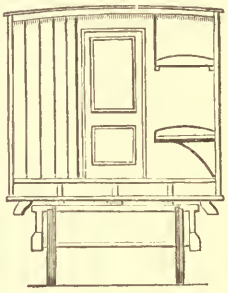

FIG. 495.—The same—transverse section.

were furnished by its Medical Director, Surgeon George E. Cooper, U. S. A. The baggage car (FIG. 493) contained three closets to store rations; the centre open space was intended to carry barrels and large stores. The two bunks shown in the transverse section (FIG. 495)

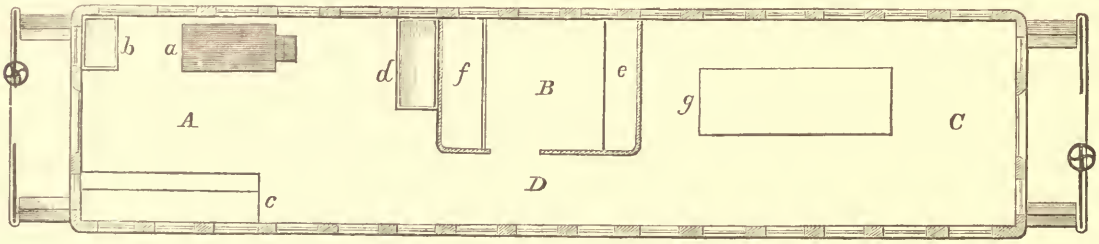

FIG. 496.—Kitchen car of the Army of the Cumberland—horizontal plan.

were for the attendants belonging to the car. The kitchen car (FIGS. 496, 497) was divided into three compartments, the dining-room, storeroom, and kitchen proper. The storeroom occupied the centre portion of the car, leaving a passage-way from the kitchen to the dining-room. The kitchen proper was furnished with a small range with boilers, etc., complete. There were stands, tables, and a closet for kitchen utensils in the kitchen proper. The letters indicate: A, kitchen, *a*, cooking range; *b*, sink; *c*, cupboard; *d*, table and shelves. B, store-room; *e*, ice-box; *f*, shelves for provision. C, dining-room; *g*, table, surrounded by benches. This apartment contained also a stove and wood-box. The car answered well the purpose required and gave perfect satisfaction.

The passenger car with seats was occupied by those not confined wholly to their beds,

and others, men furloughed from general hospitals, etc., who did not ordinarily require them at all. The five bed-cars were first-class passenger cars transformed into hospital wards.

The surgeon's car was an ordinary passenger car with the seats removed and with partitions and fixtures introduced for the accommodation of the surgeon in charge of the train and his medical assistant; there was also a small dispensary and an office for the transac-

FIG. 497.—Kitchen car of the Army of the Cumberland—longitudinal section.

tion of business (FIGS. 498, 499). The letters indicate: A, dispensary and steward's quarters; *a*, desk and book-case; *b*, shelves for medicines. This apartment contained also a revolving chair at the desk and a bed for the steward. B, surgeon's sitting-room; *d*, lounge;

e, water-closet; *f*, clothes closet. C, surgeon's bedroom; *c*, bed. D, office; *g*, lounge; *h*, water-cooler; *i*, wood-box and stove. E, wash-room, with water basin, tank, and dressing

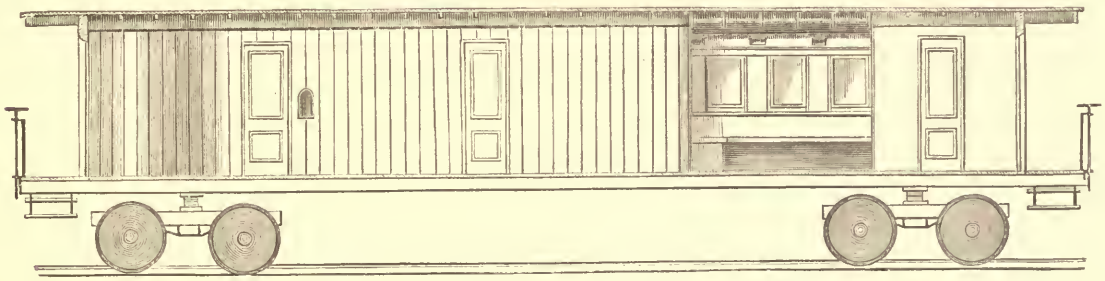

FIG. 499.—Surgeons' car of the Army of the Cumberland—longitudinal section.

locker. F F, passage through car. G, water-closet. The conductor's car in the rear was similar to the car so called attached to freight trains on ordinary railroads. It was appropriated to the use of the conductor and the citizen employés running the train. The hospital cars were warmed and lighted in the winter in the same way as passenger cars on our railroads. The same means were adopted in some cars as were in use in general hospitals, combining warming and ventilation. The hospital wards were originally those cars in which the central portion of the roof was raised considerably above the general plane; by opening the windows occupying the space between the planes very perfect ridge ventilation was obtained. The wards had also such other means of ventilation as were in use in

first-class passenger cars. If necessary, except in the coldest weather (and the seasons were mild in this climate), the car doors could be thrown open for a few minutes, at intervals, which rapidly supplied a fresh atmosphere.

The surgeon in charge of a hospital train was its sole head, the same as on a hospital transport or in a general hospital. He had a citizen conductor and engineers, firemen, and brakemen, employed by the Quartermaster's Department, who, under the immediate control of the conductor, moved the train when and wherever he ordered it. Unlike the chief medical officer of a hospital transport, he was not required to act as a commissary of subsistence or an assistant quartermaster. He drew his rations from time to time as in a general hospital. One medical assistant and one hospital steward was ordinarily all that were required on a train. Enlisted men were detailed as cooks, nurses, and hospital attendants. Only a limited number of the latter were required, and those not on duty occupied beds, if necessary, kept vacant in one of the wards. The needful washing of bedding, etc., was done at one of the termini of the route.

In the spring of 1864, and during the advance of General Sherman's army on Atlanta, Georgia, and while that place was occupied by General Sherman previous to his cutting loose from all communication with the north and striking across the country to Savannah, three hospital trains ran regularly between Louisville, Kentucky, and Atlanta, Georgia, a distance of four hundred and seventy-two miles, viz: Train No. 3, from Louisville, Ken-

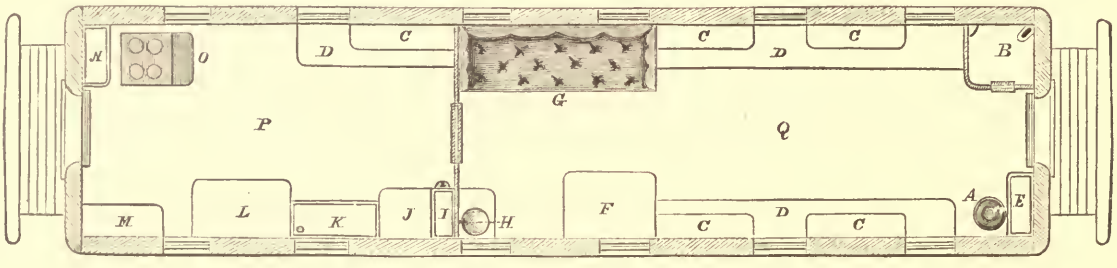

FIG. 500.—Kitchen and dispensary car, Army of the Potomac—horizontal view.

tucky, to Nashville, Tennessee, distance one hundred and eighty-five miles; train No. 2, from Chattanooga, Tennessee, to Atlanta, Georgia, distance one hundred and thirty-six miles. These trains passed over the road once every day—down one day and returning the next. Train No. 1 connected with No. 3 at Nashville, and with No. 2 at Chattanooga, on

FIG. 501.—Kitchen and dispensary car, Army of the Potomac—longitudinal view.

alternate days. A time-table was prepared by which the running of the hospital trains was regulated—which was adhered to for some time. Sick and wounded in the sanguinary engagements of this eventful campaign were taken from the large hospital depots at Atlanta, Marietta, Kingston, and Rome, Georgia, to the permanent hospitals at Chattanooga and Nashville, Tennessee, and Louisville, Kentucky. Some men were brought directly through

from Atlanta, Georgia, to Louisville, Kentucky, over this long span railway line, stretching south four hundred and seventy-two miles to the distant army. If necessary, a ward in one train was uncoupled and attached to the connecting train without disturbing the patients. The ordinary *modus operandi* in railroad transportation was to empty the hospitals at Nashville and Chattanooga of men partially recovered, and who would not be injured by moving, and take them up to Louisville. The beds thus vacated at these points were filled from below.

In the Army of the Potomac the complete hospital train consisted of twelve cars—one for the surgeon in charge, one for the kitchen and dispensary, and ten for the sick and wounded. The cars fitted up for the carrying of patients have been described on page 961. The kitchen and dispensary (FIGS. 500, 501) car was built according to plans prepared by the Assistant Superintendent of Military Railroads, J. McCrickett. The car was divided into two compartments. The dispensary contained a stove, A; a water-closet, B; cases for shelves, C; cases of drawers, D; wood-box, E; table or desk, F; couch, G; wash-basins, H. In the kitchen, P, were: C, cases of shelves; D, cases of drawers; I, water-cooler; J, refrigerator; K, sink for washing dishes; L, table; M, pantry; N, wood-box; O, cooking-stove.

WATER TRANSPORTATION.

The military operations in the western departments in the spring of 1862 embraced a large extent of territory and necessitated the moving of large bodies of men from point to point. As a result, the fresh unacclimated levies fell victims to malignant fevers, diarrhœa, dysentery, etc. The resources of the Medical Department under these circumstances were entirely inadequate to the pressing necessities. It became evident that to disembarrass the medical officers and to have them in readiness for the exigencies of battles, which all knew were impending, the sick must be removed to points remote from the scene of operations. For this purpose the large rivers of the Western States, especially the Mississippi, offered the best facilities. But there were no transports at the disposition of the medical officers. In order to send a single sick soldier it was necessary to apply to the quartermaster of the army, who naturally gave the preference to his immediate duties, and even when, after much circumlocution, a boat was secured and partly filled with patients, it was frequently delayed until the demands of other departments were complied with. The necessities of the sick and wounded were of a secondary consideration, and the surgeon who exerted himself in the interest of common humanity was regarded as asking favors for himself. The fact that the efforts of the Medical Department were thus paralyzed was brought to the notice of the General Commanding by Surgeon J. Simons, U. S. A., Medical Director, who recommended that a suitable number of boats be taken and fitted up comfortably with beds, cooking apparatus, surgeons, and nurses, etc. The appeal was favorably received, and several steamers were chartered and placed under the charge of medical officers. We will quote from the excellent report of Surgeon A. H. Hoff, U. S. V., master of hospital transportation on the Mississippi, made in September, 1863: "The City of Memphis, a very large and fine steamer, was chartered, and Assistant Surgeon W. D. Turner, 1st Illinois Light Artillery, placed in charge. The steamer City of Louisiana was also chartered and fitted up under the control of Assistant Surgeon C. Wagner, U. S. A., and, with the City of Memphis, was at once employed in the carrying of sick and wounded. About the 1st of April, 1862, after the experiment had been made and proved successful,

Surgeon Simons requested that boats be purchased and fitted up as floating hospitals. On his report and the co-operation of Mr. Yeatman, the President of the Western Sanitary Commission, the steamer D. A. January was purchased and placed in my charge. This boat, on account of her light draught and airy cabin, was well suited for the purpose. There was no time to make more than temporary arrangements, and she was not reconstructed until September, 1862, when she was fitted up with every convenience as a hospital. These boats proving inadequate to supply the amount of transportation required, two of the largest steamers on the river were chartered (the Empress and Imperial) and temporarily fitted up, and Surgeons T. F. Azpell and J. H. Grove, U. S. V., were placed in charge of them. The transportation still being insufficient, the steamers Stephen Decatur and J. S. Pringle were added to the list, and these, together with the several boats sent by different states, made quite a formidable fleet; yet they all had plenty of employment, as sick and wounded had to be transferred to the number of thousands. These boats, as they ceased to be needed, were discharged, leaving the D. A. January alone. As the hospital accommodations at Pittsburg Landing were very imperfect, Medical Director Charles McDougall, Surgeon, U. S. A., requested the construction of a floating hospital, which could be towed from point to point, to be used as a receiving hospital, from which the transports could load and in which the sick and wounded could be placed and made comfortable in the absence of the transports. In this he was finally successful, and the hulk of the steamer Nashville was purchased and fitted up so that she would be able to receive in an emergency one thousand men, and Surgeon Strawbridge, U. S. V., was placed in charge. She was towed to Milliken's Bend, La., and was of great service, as the submerged condition of the country made it impossible to care for the sick on shore. Up to this time, although the Assistant Surgeon General, on taking charge of the Western Department and visiting the scene of active operations, repeatedly urged the purchase of more steamers for hospital purposes, for some reason, unknown to him as well as to others, he was unsuccessful; but the unsuccessful attack on Vicksburg, in December, the battle of Arkansas Post, and the advance of the whole army in the direction of Vicksburg made it necessary to again resort to chartering transports. The City of Memphis and City of Alton were again temporarily fitted up, and with the D. A. January transferred the sick and wounded from Milliken's Bend, Young's Point, and Sherman's Landing, to Memphis and St. Louis. In the meantime, however, several boats had been taken—the steamers Von Phul and J. C. Swon, in fact at least one-fourth of the returning transports—without a single comfort for the sick and wounded on board, were made use of to transfer them to the general hospitals North. Under such circumstances the suffering was terrible and the mortality frightful. I am not disposed to find fault, nor do I wish to censure any one, but I feel it my duty to remark that the Medical Department did everything in their power to correct this matter, with but poor success. The Assistant Surgeon General, never tiring in his determination to push this matter, finally succeeded in getting the City of Louisiana purchased and fitted up in a most comfortable manner, with good accommodations for four hundred, with every improvement that a year's experience could suggest. During this time the Navy had fitted the Red Rover in a most elegant and substantial manner; the Marine Brigade also fitted the Woodford as a hospital with every comfort that could be made available. The U. S. Hospital Steamer D. A. January having run for a year and a half it became necessary to repair her, and upon examination new boilers were found to be necessary. As we came in possession of more of the Mississippi additional accommoda-

tions for the comfort of the sick and wounded were required. Under these circumstances the January was reconstructed, better ventilation secured, better and more convenient arrangements for cooking were made, and a fan, one hundred and sixty feet long and propelled by machinery, was placed in the main ward for the purpose of cooling the atmosphere and as a means of ventilation. It answered an admirable purpose and did away with the necessity of covering the decks with an awning, which was not only difficult but a very expensive matter. After her reconstruction her name was changed to Charles McDougall, in honor of Surgeon McDougall, U. S. A., who had interested himself when Medical Director of the Department in securing proper transportation for the sick and wounded, and by whose request she was finally fitted with all the conveniences for a hospital transport.

"It would be impossible for me, not being in possession of records, to give any idea of the number of sick and wounded transferred—nor do I believe it would be possible, from the fact that emergencies required boat after boat to be made use of where no record was kept to give the exact figures—suffice it to say that the U. S. Hospital Steamer Charles McDougall (D. A. January) carried from April 5, 1862, to September 12, 1863, twelve thousand two hundred and ninety-nine sick and wounded to the several general hospitals, she being constantly employed. A fair average may be made by taking into calculation the time the other boats were employed, most of them probably carrying more at each load. The use of steamers for hospital purposes being a new thing, changes in the arrangements were required as the necessities became apparent. Orders were made by the chiefs of the several Departments of such a character as would secure prompt attention on the part of all their subordinates and at the same time place the surgeons in charge in such a position that the least possible delay should occur. Believing it to be of interest and forming a part of the success of the subject to which this history relates, I will append these orders as they were made from time to time. The first great difficulty to be overcome was to do away with the idea that as these boats were for the transportation of the sick and wounded they were the vehicles for carrying not only all the friends of the sick and wounded, but every man, woman, and child who became impressed with the slightest inkling that their hearts contained one particle of sympathy for the poor soldier; curiosity seekers, sanitarians, state agents, sutlers, committees from various associations, one and all concluded they had a right to transportation on such a boat. This of course was out of the question, as it prevented the employés from properly cleaning the boat and took up room required for patients. More than this, it used up the subsistence which belonged to the hospital fund, which was used to buy so many things necessary for the diet of the sick. It was annoying to the surgeons, it was in the way of all discipline, and in fact disagreeable to every one. Under these circumstances Major General Halleck issued the following order:

'HEADQUARTERS, DEPARTMENT OF THE MISSISSIPPI,
PITTSBURG LANDING, TENNESSEE, *April* 20, 1862.

Surgeon Simons has authority to prevent persons from travelling on hospital boats.
BY ORDER OF MAJOR GENERAL HALLECK: (Signed) A. C. KEMPER,
Assistant Adjutant General.

No person will hereafter be permitted on floating hospitals except by permission of the Surgeon in charge. (Signed) J. SIMONS, *Surgeon of Army, Medical Director.*'

"This left the Surgeon in charge an opportunity of using his discretion in reference to who should travel on his boat, and, I think, in most instances it has been confined to medical officers who could assist instead of being in the way.

"The next important step was to be arranged with the Subsistence Department. This was surrounded with some difficulties, as there was no room on board for a commissary. The difficulty was soon remedied by making the Surgeon in charge an Acting Assistant Commissary of Subsistence, thereby enabling him to receive subsistence from any commissary by invoice and receipt, and to purchase such articles as the sick required.

'CAIRO, ILLINOIS, *April* 7, 1863.

SIR: By authority from Major General Halleck, commanding the Department of the Mississippi, Surgeons in charge of hospital boats will act as A. A. C. S., so far as receiving and issuing stores for the hospital under their charge is concerned.

Respectfully your obed't servant,

B. DUBARRY,
Capt., &c., C. S., U. S. A.

To Surgeon in charge of hospital boat D. A. January.'

"By a similar order the surgeon was held responsible for all the property belonging to the Quartermaster's Department in his charge, and required to receipt for it. This, of course, was an anomaly in departmental matters, but one that was required for the proper administration of the affairs of the floating hospitals; without such an arrangement the unavoidable delays would have destroyed their efficiency. The Medical Department is much indebted to Major Generals Halleck and Grant for the kindness shown and interest taken by them in this branch of the service. We are also indebted to Quartermasters, Brigadier General Allen and Colonel Myers, and to Colonel Parsons, in charge of the river transportation, for their uniform kindness and assistance in the purchase and reconstruction of the boats; also to Colonel Haines, Chief Commissary, for the liberal manner in which the boats have been supplied with subsistence, and, through his orders, the little delay occasioned in receiving supplies. In fact, all have wished us a 'God speed' in a work which has been the means of relieving so much distress and probably of saving many lives."

Steamer City of Memphis.—The first boat chartered on the western rivers for the transportation of wounded was the steamer City of Memphis, which was taken into the service as a hospital boat at Fort Henry on February 7, 1862, by order of Major General U. S. Grant, and placed under the charge of Assistant Surgeon W. D. Turner, 1st Illinois Light Artillery. She was fitted out as thoroughly as circumstances permitted. Spring mattresses were placed on the floor of the upper deck and saloon; the state-room was rearranged, and medicine and commissary stores supplied. Her length was three hundred and thirty feet and her beam seventy feet; her main deck was large and roomy, and her saloon of great length, and she was capable of carrying comfortably seven hundred and fifty wounded men. From February 7th to 18th she was used as a receiving boat, conveying a large number of sick and wounded from Fort Henry and transferring them to other boats. No record of this work was kept; but the number thus transported is estimated at two thousand. On February 18th she left Fort Henry with four hundred and seventy-five sick and wounded for Paducah, Kentucky, where she arrived on February 19th; the patients were transferred to the general hospitals, and the boat left for Fort Donelson the same day and arrived there on February 21, 1862. The boat was discharged from the hospital service in July, 1862, by Medical Director McDougall, of the Army of the Tennessee, but re-engaged and employed in carrying wounded from the vicinity of Vicksburg during Grant's campaign. No record of the number transported during her second engagement is found.

From February 18th to July 19th, 1862, the boat made fourteen trips and conveyed seven thousand two hundred and twenty-one sick and wounded men, as follows:

TABLE CLXXVI.

Steamer Louisiana, afterwards named R. C. Wood.—The fast steamer Louisiana was chartered on March 12, 1862, and placed under the charge of Assistant Surgeon C. Wagner, U. S. A., who mainly furnished the data here adduced. The boat was immediately supplied with bedding and the necessary hospital commissary stores; the Western Sanitary Commission very liberally supplied many articles not procurable at the time from the Medical Purveyor. The boat was divided into four wards, two on the lower deck and two on the upper or boiler deck, each of which had a medical officer, a wardmaster, six permanently detailed male nurses, and one female nurse. The nurses were relieved from duty every six hours, day and night. Upon the lower deck was the kitchen, commissary, storeroom, bakery, and ice-house; upon the upper deck the captain's office was converted into the office of the Surgeon in charge, and the bar-room into a dispensary, the barber-shop and wash-room into a kitchen for low and half-diet patients under the supervision of a female nurse. The bulkheads between the state-rooms were removed, improving the ventilation and rendering access to the patients more easy. Beds were also placed on the guards of the boat, tarpaulins being stretched to protect the patients from the inclement weather. The texas upon the hurricane deck was used as quarters for the hospital attendants and the boat's crew. An oven was on board capable of baking bread for a thousand men daily. In admitting as well as in removing the patients a systematic arrangement was adopted. A medical officer was stationed at the gangway to receive them, one on the boiler, and another on the lower deck. Each wardmaster remained in his ward, and a sufficient number of nurses was detailed to carry the patients on or off the boat. By this arrangement all confusion was avoided; no one was admitted as a patient except upon a written order from the Medical Director. The boat at this time had accommodations for four hundred patients. She carried, in less than four months, about three thousand patients from Pittsburg Landing and other points on the western rivers to northern hospitals, and was released from service during the summer of 1862. An account of the trips is taken from the report of Assistant Surgeon C. Wagner, U. S. Army:

TABLE CLXXVII.

Tabular Statement of Trips made by the Steamboat Louisiana from March 23 to June 14, 1862.

In April, 1863, the boat was purchased by the Government and remodelled as a permanent hospital boat, with beds for four hundred and fifty patients, and was named the 'R. C. Wood,' in honor of the Assistant Surgeon General of the United States Army, to whose wisdom, humanity, and constant foresight many of the improvements in the hospital arrangements were due. Surgeon T. F. Azpell, U. S. V., was placed in charge. Her state-rooms were removed, the whole upper deck was made into one large ward, with abundant light and excellent means of ventilation, with ample provisions of bath-rooms, hot and cold water, cooking apartments, nurses' rooms, dispensary, laundry, and many other conveniences.[1] Her length was two hundred and fifty feet, beam forty feet, hold seven feet. From April, 1863, to April 11, 1865, this boat made thirty-three trips, travelled thirty-four thousand eight hundred and five miles, and carried eleven thousand and twenty-four (11,024) sick and wounded, as follows:

TABLE CLXXVIII.

Statement of Trips made by the Hospital Steamboat R. C. Wood from April 1, 1863, to April 11, 1865.

No. of Trip.	Date of Departure.	Place of Departure.	Place of Arrival.	No. Sick and Wounded.
1	April 1, 1863	Milliken's Bend	Saint Louis	107

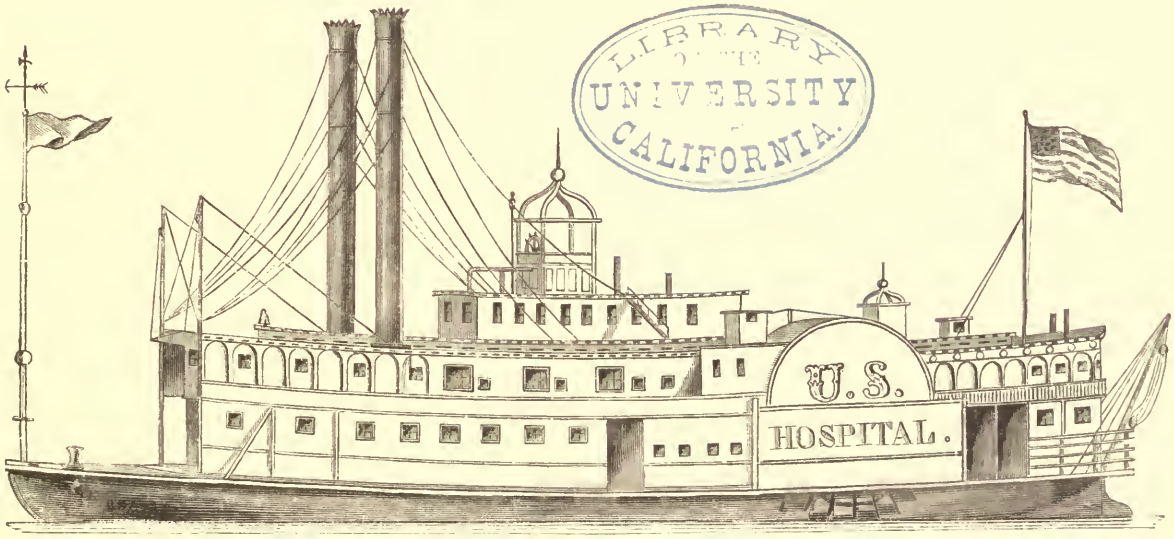
With the two thousand nine hundred and ninety-nine (2,999) patients carried during her first engagement, from March 23d to June 14, 1862, the boat altogether conveyed fourteen thousand and twenty-three (14,023) sick and wounded from the scene of action to northern hospitals.

Perhaps the most perfect of the western hospital boats was the steamer 'D. A. January.' She was purchased on April 1, 1862, and placed under the orders of Assistant Surgeon A. H. Hoff, U. S. A. She had been built at Cincinnati in 1857. She was a side-



LIBRARY OF THE UNIVERSITY OF CALIFORNIA

FIG. 502.—U. S. Army Hospital Steamer D. A. January.

wheel steamer of four hundred and fifty tons burden, two hundred and thirty feet in length, thirty-five feet beam, and sixty-five feet extreme width. She had two high-pressure engines, with cylinder twenty-two inches in diameter and seven feet stroke. As a precautionary measure against accident by fire, she had a small steam fire engine, which worked independently, and was supplied with sufficient hose. During the summer of 1862 the boat carried patients from Pittsburg Landing, Paducah, and Helena, to St. Louis, Keokuk, New Albany, and Cincinnati. In the fall of 1862 she was entirely remodelled under the supervision of Assistant Surgeon A. H. Hoff, to whom the department is indebted for many important suggestions, especially in the earlier days of hospital transportation. On the

hurricane deck (FIG. 503), the roof of the boat, was the texas, on top of that the pilot-house. The staterooms were taken out and the whole cabin deck converted into one spa-

a nurses' dining-room, a bath-room, and water-closet, and on the other a special diet kitchen, bath and wash-room, and water-closet. Away aft there was on one side a drug-shop and steward's room, on the opposite side a linen-room, in the centre an operating-room. Drinking-water throughout the ward was drawn from faucets placed at convenient distances. The bath-rooms were supplied with water from a large tank on the hurricane deck, filled

with water by steam-power. The drinking-water arrangement was a refrigerator on a large scale. Pipes ran from the tank on the hurricane deck into two large ice-chests in the hold of the boat, one on each side. In these chests were large worms through which the water

passed and was carried through the different wards, furnishing iced water, or water cool enough for all purposes. By this plan a large amount of ice was saved, as the chests were seldom opened.

Between the main and the boiler decks, on the middle deck (FIG. 505), where the wood-racks used to be, two wards, one on each side, were arranged, containing thirty beds each, with water-closets, wash-troughs, and faucet for drinking-water. The wards were low, but the bulkheading was composed almost entirely of windows, so that plenty of air could circulate. On the lower deck (FIG. 506) there was a comfortable ward for one hun-

dred beds, water-closets, and wash-troughs; a large kitchen connected with the wards on the upper decks by a dumb-waiter; a bakery on one side, a blacksmith shop, carpenter shop, and commissary room on the other. Through the whole length of the main ward ran a fan, worked by steam from below (it made about ninety revolutions a minute), and as the transom windows opened just above it, at the sides, it created a pleasant current of air and kept out all flies and mosquitoes. This boat carried from April, 1862, to August, 1865, altogether twenty-three thousand seven hundred and thirty-eight patients, as follows:

Steamer Empress.—The steamer 'Empress' was chartered on April 10, 1862, and placed in charge of Surgeon Thomas F. Azpell, U. S. V. Being built expressly for a cotton boat, and said to be the largest engaged in that trade, she was found to be admirably adapted to hospital purposes. Her capacious dimensions and the unusually large area on each deck, which could be used for beds, rendered her accommodations for the sick unsurpassed. Her cabin was small, containing only forty state-rooms, which were principally used by the hospital corps in consequence of their imperfect ventilation. Canvas flies on the upper and tarpaulins on the lower deck completely protected the guards from the weather. Her length was two hundred and sixty-six feet, width of beam forty-five feet, depth of hold eight feet three inches. Her carrying capacity was five hundred patients, but this number could be largely increased in mild weather. The largest number she carried on one trip was eight hundred and seventeen. The 'Empress' made six trips, but her draught of water was such as to render her unfit for the navigation of the Tennessee and Cumberland rivers during their low stage. She was therefore discontinued as a floating hospital in June, 1862.

Steamer Imperial.—On April 10, 1862, the steamer 'Imperial,' a new and very large boat, was fitted up as a transport for sick and wounded by Surgeon J. H. Grove, U. S. V. She made four trips, carrying one thousand seven hundred and eighty-one (1,781) patients, but her services were discontinued on May 17, 1862, as her draught of water was too great for the low state of the Tennessee River during the summer season.

Other steamers employed on the western waters were the 'City of Alton,' the 'Baltic,' the 'Ginnie Hopkins,' the 'Mercury,' 'Woodford,' 'Decatur,' 'Pringle,' 'Nashville,' etc. Space will not permit to enter in detail into a description of these boats or the nature of their service.

In the eastern armies, although many boats were temporarily employed for the purpose of conveying sick and wounded, few were fitted up as regular hospital transports. In the early summer of 1862, when the scene of active operations was transferred from the interior of Virginia to the eastern seaboard on the Peninsula, it became evident that unusual means would be required to remove the sick and wounded as fast as possible from these malarial

districts to healthier localities. The boats used for the transport of troops were all under the immediate direction of the Quartermaster General. On application to the Secretary of War quite a number were turned over to the medical authorities, but these boats were destitute of all conveniences. Perhaps the earliest boat thus assigned in the latter part of April, 1862, was the 'Daniel Webster.' She was entirely without mattresses, bedding, medicine, and surgical appliances, but was hastily fitted up by the Sanitary Commission, filled with patients, and, on May 1st, left the York River for New York. The 'Ocean Queen,' a large, commodious vessel, capable of carrying comfortably one thousand patients, was, a few days later, also turned over to the Medical Department and fitted up by the Sanitary Commission. When received there was not a bunk nor an article of food on board. The 'Ocean Queen' took about nine hundred patients to New York, but, on her arrival there, was withdrawn from the hospital service and sent with troops to the Gulf of Mexico.

The principal boats employed in the eastern waters, besides the two already mentioned, were the 'Connecticut,' 'State of Maine,' 'Western Metropolis,' 'De Molay,' 'Spaulding,' 'Baltic,' 'Atlantic,' 'J. K. Barnes,' 'Commodore,' 'Cosmopolitan,' 'Knickerbocker,' 'Elm

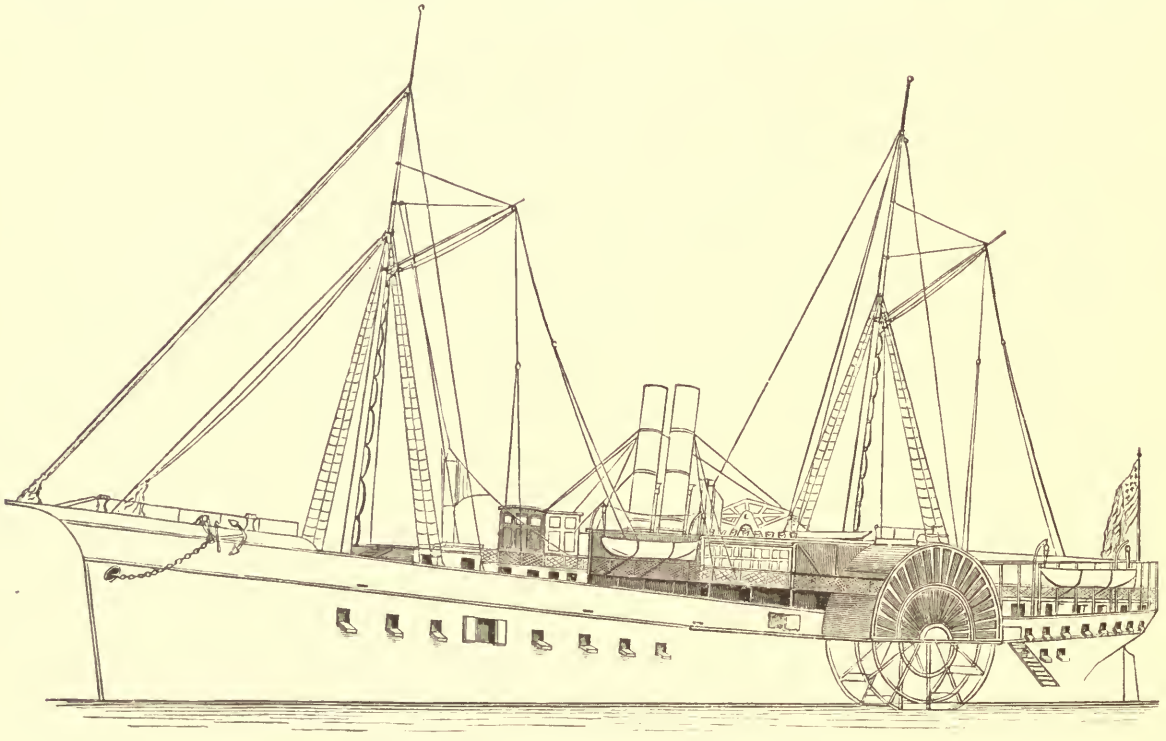

FIG. 507.—U. S. Hospital Steamship 'J. K. Barnes.'

City,' etc. The capacity of the 'Connecticut' was four hundred patients. She made altogether forty-seven trips and conveyed eighteen thousand nine hundred and nineteen (18,919) patients. The capacity of the 'State of Maine' was three hundred patients, and she carried in forty-eight trips fifteen thousand seven hundred and eleven (15,711) patients. The capacity of the 'Western Metropolis' was four hundred and fifty patients, of the 'De Molay' three hundred, of the 'Baltic' five hundred, and of the 'Atlantic' five hundred patients. Some of these boats were employed on the inland waters, others, like the 'Western Metropolis,' 'De Molay,' 'Cosmopolitan,' and 'Baltic,' conveyed the wounded from all points along the Middle and Southern Atlantic coast to Philadelphia, New York, and points in the North and East. Of the latter class was the 'J. K. Barnes,' fitted up

in New York city during the latter part of 1864, under the supervision of Assistant Surgeon A. H. Hoff, U. S. A., to whose large experience in the transport of the sick and wounded in western waters we have had occasion to allude. The 'J. K. Barnes' was two hundred

One of the greatest difficulties that the Medical Department had to contend with in the early part of the war was its want of control over the hospital transports. Many boats were assigned for the conveyance of wounded, but no sooner had they been fitted up and had made a few trips than they would be claimed by the Quartermaster's Department, by which they had originally been chartered, as transports for troops. When they were finally returned to the Medical Department they had been stripped of all the appurtenances for the comfort of the sick, thus necessitating their refitting at enormous costs. This anomalous condition continued until November, 1863, when the hospital steamer 'Cosmopolitan,' which had been used in transporting sick from one point to another in the Department of the South, was taken away from the Medical Department and turned back to the Quarter-

master's Department by order of Major General Gilmore. The Acting Surgeon General requested the return of the steamer to the Medical Department, which being referred to General Gilmore for remark, he replied that the vessel was only temporarily loaned to the Medical Department, and that "as commanding officer of the department I hold myself responsible for the administration of its internal affairs, and consequently assume the right to apply its resources as the exigencies of the service may seem to require."[1] To this endorsement the Acting Surgeon General replied, on December 25th, in the following letter to the Secretary of War:

"SURGEON GENERAL'S OFFICE,
"*December* 25, 1863.

"SIR: I have the honor to acknowledge the receipt of Major General Gilmore's endorsement upon my application for the restoration of the steamer Cosmopolitan to the Medical Director, stating that 'the steamer Cosmopolitan belongs to the Quartermaster's Department, and was placed at the disposal of the Medical Director for temporary purpose by orders from these headquarters.'

"In the request of November 24th no question was made of the power of the general commanding the department to dispose of the steamer, but the necessity for her services was stated as a reason for her restoration. The Cosmopolitan was selected by the then Medical Director, under orders from Major General Hunter, and by his orders was fitted up and especially assigned to the Medical Department as a hospital steamer, and *not* as a temporary transport. All hospital steamers are owned or employed by the Quartermaster's Department, but their outfits and movements are under charge of the Medical Department. Upon the only occasion of emergency when Major General Hunter used the Cosmopolitan as a dispatch boat he did so after advisement with his Medical Director * * * *

"Very respectfully, your obedient servant,

(Signed) "J. K. BARNES,
"*Acting Surgeon General.*"

The Secretary of War directed the steamer to be returned to the Medical Department, which was accordingly done; but in the following June she was again taken from it by General Hatch, and much suffering to the sick and wounded resulted. A similar interference with the Medical Department in the case of the hospital steamer 'Spaulding' was reported to the Surgeon General by Medical Inspector G. H. Lyman, in December, 1864. This report was forwarded to the Secretary of War with the following endorsement:

"Respectfully forwarded to the Honorable Secretary of War, with the urgent request that orders may be issued prohibiting interference with hospital transports by other departments.

"The hospital transport Spaulding has just been fitted up at great expense, and was dispatched to meet General Sherman's army upon notification of its arrival at Savannah. To divert it to other purposes entirely cripples this Department in its efforts to provide properly for the sick and wounded, and subordinates all its interests to the caprice or whim of local commanders.

(Signed) "J. K. BARNES,
"*Surgeon General.*"

"S. G. O., *January* 3, 1865."

On January 23, 1865, the Surgeon General addressed a further letter to the Secretary of War on this subject, of which the following is a copy:

"SURGEON GENERAL'S OFFICE,
"*January* 23, 1865.

"SIR: From the nature of the service upon which they are employed it is absolutely essential that hospital transports and hospital boats should be exclusively under the control of the Medical Department, and not, under any circumstances, diverted from their special purposes by orders of local commanders or officers of other departments. I have, therefore, the honor to request that

[1] BROWN (H. E.), *The Medical Department of the United States Army from* 1775 *to* 1873. Washington, D. C., 1873, page 243.

orders to this effect be issued, and that the hospital steamer Cosmopolitan be restored to the Medical Department and placed under the immediate control of the Medical Director, Department of the South, at Hilton Head, South Carolina, to be used as a hospital tender for the troops operating under Major General Sherman in that department.

"Very respectfully, your obedient servant,

(Signed) "J. K. BARNES,
"*Surgeon General.*"

In accordance with this request the following order was issued on February 8th:

"WAR DEPARTMENT, ADJUTANT GENERAL'S OFFICE,
"WASHINGTON, *February* 8, 1865.

"GENERAL ORDERS No. 18.

"Hospital transports and hospital boats, after being properly assigned as such, will be exclusively under the control of the Medical Department, and will not be diverted from their special purposes by orders of local or department commanders, or of officers of other staff departments.

"BY ORDER OF THE SECRETARY OF WAR.

(Signed) "E. D. TOWNSEND,
"*Assistant Adjutant General.*"

This order effectually ended the interference of local or department commanders and vested the control of the hospital transport steamers where it properly belonged—*i. e.*, in the Medical Department.

LIST OF PLATES.

1. PLATE XXVIII, facing p. 18. GANGRENE FOLLOWING A SHOT LACERATION OF THE FEMORAL ARTERY. Case of G. W. Gardner, page 18. (Chromolithograph.)

2. PLATE LVI, facing p. 27. DRY TRAUMATIC ARTHRITIS OF THE RIGHT HIP. Specimen 5518. Case of Albert McGee, page 27. (Heliotype.)

LIBRARY OF THE UNIVERSITY CALIFORNIA

SUBJECT-MATTER INDEX

OF THE

THREE VOLUMES OF THE SURGICAL PART

OF THE

MEDICAL AND SURGICAL HISTORY OF THE WAR OF THE REBELLION.

Abdomen, injuries of, II, 1–208; III, 689. *Parietal wounds,* II, 3; punctured and incised wounds, II, 302; sabre wounds, II, 3, 8; III, 686; rupture and protrusion of intestines after sabre wound, II, 3; bayonet wounds, II, 3, 8; III, 686; other punctured and incised wounds, II, 4, 8; III, 653; lacerated and contused wounds, II, 4, 8; rupture of muscles, II, 5. *Shot flesh wounds,* II, 6; III, 689; mortality rates of, II, 7; tabular statement of injuries of parietes, II, 8. *Complications of parietal wounds,* II, 8; hæmorrhage, II, 8; foreign bodies, II, 11; gangrene, II, 8, 12; hernia, II, 13; nervous disorders, II, 13; tetanus, II, 14. *Shot contusions,* III, 689. *Visceral injuries without external wounds,* II, 15–28; III, 689; tabular statement of, II, 26; diagnosis and treatment of, II, 27–28; ruptures of liver, II, 16; of spleen, II, 18; of kidney, II, 20; of stomach, II, 22; of intestines, II, 22; of omentum and mesentery, II, 23; of blood-vessels, II, 24; of diaphragm, II, 25. *Penetrating wounds,* II, 29; III, 689; penetrations without visceral injury, II, 29–40, 202; by bayonet, II, 31–33, 39; by arrow, II, 33; by ramrod, II, 33; shot wounds, II, 34–39; III, 689; autopsies, II, 32, 36. Diagram of subdivisions of abdominal region, II, 97. Injuries of abdomen involving stomach, see **Stomach;** involving intestines, see **Intestines;** involving liver, see **Liver;** involving pancreas, see **Pancreas;** involving spleen, see **Spleen;** involving kidneys, see **Kidneys;** involving supra renal capsules, see **Supra Renal Capsules;** involving omentum, mesentery, and blood-vessels, see **Omentum, Mesentery,** and **Blood-vessels.** *Complications of penetrating wounds of the abdomen.* II, 176; hæmorrhage, II, 176; foreign bodies, II, 179; visceral protrusions, II, 180; hernia, II, 184; abdominal effusions, II, 188; air or gases, II, 198; traumatic peritonitis, II, 199. *Frequency of* wounds of abdomen, II, 201; mortality, II, 202; diagnosis and treatment, II, 206–207.

Abdominal Effusions, II, 188; of blood, II, 189, 190; of bile, II, 192; of urine, II, 193; of fæces, II, 194; of pus, II, 197.

Abscess, in shot wounds of head, I, 127; in cerebrum, I, 327; air passing through opening in abscess of neck, I, 360; abscess around balls, I, 404; metastatic abscesses of lung, I, 626, 628; II, 841, 844, 920; III, 431, 455; of liver, I, 443, 585; II, 216, 772, 781, 843; III, 431, 547; of spleen, II, 151, 813; III, 547; of kidney, II, 171.

Acetabulum, shot fractures of, II, 179; III, 65, 68, 78–79, 80, 81.

Acromial Thoracic, aneurism of, III, 808; hæmorrhage from, II, 459; III, 764; ligation of branch of, II, 632; III, 765, 776.

Actual Cautery in hæmorrhages, II, 320, 456, 736; III, 811.

Acupressure, III, 811.

Air, accumulation of, in abdomen, II, 198.

Air Passages, operations on, I, 415; III, 684.

Amaurosis in wounds of head, I, 38, 116, 178, 208, 228, 232, 289; produced by wind of shell, I, 344.

Ambulance Corps, III, 931–943; officers of, III, 913, 914; plans for organization of: by Dr. H. H. SMITH, III, 932; Surgeon B. A. VANDERKIEFT, III, 935; C. PFIRSCHING, III, 932; organization and management of, III, 935, 938, 939, 941; act of Congress establishing, III, 941, 943.

Ambulance Train, III, 902.

Ambulance Wagons, III, 944–957; MOSES, III, 945–946; FINLEY, two-wheeled, III, 946; COOLIDGE, two-wheeled, III, 947; TRIPLER, III, 947; ROSECRANS, III, 948; COOLIDGE, four-wheeled, III, 949; SÜS, III, 951; ARNOLD, III, 951; MCKEAN, III, 952; PEROT & CO., III, 952; RUCKER, III, 952; HOWARD, III, 953; LANGER, III, 955; Confederate, III, 956.

Amputations, analysis of total number of, III, 877–886; mortality rates of, III, 878; primary amputations, III, 879; intermediary, III, 879; secondary, III, 879; methods of, III, 880; double amputations, III, 880. See **Shoulder Joint, Arm, Elbow Joint, Forearm, Wrist Joint, Hand, Fingers, Hip Joint, Thigh, Knee Joint, Leg, Ankle Joint, Foot, Toes, Penis.**

Anæsthetics, III, 887–898; number of cases of, III, 887; agents used, III, 887; mode of administering, III, 889; MARSHALL HALL'S mode, III, 889; administered by CHISOLM'S inhaler, III, 889; deaths from, III, 890–895; restoration of animation suspended by anæsthetics, III, 895; cases of anæsthetics in the U. S. Army since the war, III, 896; chloroform, III, 897; ether, III, 897; chloroform and ether, III, 897; prostration following anæsthesia, III, 897; excitement, III, 897; vomiting, III, 897.

Anal Fissure, treated by incision or by rupture of the sphincter, II, 321.

Anal Fistula, number of instances of, II, 321; treatment of, II, 321.

Anaplasty, cases of, II, 77, 79, 91; unnecessary and ineffectual, II, 111.

Anastomotica Magna *of brachial,* wounds of, II, 457; III, 764; ligation, II, 454; III, 765, 782; *of femoral,* hæmorrhages from, III, 764.

Anchyloblepharon, operation for, III, 683.

Aneurism, traumatic, III, 808; of acromial thoracic, III, 808; aorta, II, 189; axillary, II, 468; III, 808; brachial, II, 463, 468; III, 680, 808; carotid, II, 499; III, 679, 808; circumflex, III, 808; femoral, III, 38, 39, 40, 42, 45, 46, 808; iliac, III, 808; innominata, III, 808; intercostal, II, 597; interosseous, III, 808; superior mesenteric, II, 25; peroneal, III, 808; popliteal, III, 14, 680, 808; profunda, III, 49, 808; pudic, II, 252; III, 808; radial, II, 969, 1010; III, 808; sciatic, III, 808; subclavian, II, 632, 634, 635; III, 808; suprascapular, III, 808; tibial, III, 55, 673, 808; diffuse traumatic aneurism, I, 446, 555; III, 755; following bayonet wounds, II, 323, 335.

Ankle Joint, wounds and operations of, III, 577–616; shot injuries of, III, 577, 608–610; periarticular wounds of, III, 31, 690; shot contusions of, III, 577, 690, 716; shot fractures of, III, 578, 690, 870; treated by conservation, III, 579; treated by excision, III, 585, 610–612; primary excisions, III, 586; intermediary excisions, III, 588; secondary excisions, III, 591; autopsy, III, 590; treated by amputation, III, 595, 608, 612, 616; primary amputations, III, 596, 598; intermediary amputations, III, 603; secondary amputations, III, 606; SYME'S operation, cases of, III, 596–615; PIROGOFF'S operation, cases of, III, 596–615; BONTECOU'S modification of PIROGOFF, cases of, III, 604, 605, 606; BAUDEN'S operation, cases of, III, 604; modification of SYME, cases of, III, 601; amputations following excisions, III, 870; re-amputations following amputations at ankle, III, 870; miscellaneous injuries of ankle joint, dislocations, III, 648; fractures, III, 652; excisions of, III, 657–658, 659; amputations at, III, 664.

Antiseptic treatment of wounds on field of battle, III, 418, 419.

Anus, abnormal, II, 109; instruments for destroying septum: DUPUYTREN'S enterotome, BLASIUS' intestine pincers, GROSS'S, REYBARD'S instruments, II, 110, 111; DESAULT'S operations on abnormal anus, II, 113; PALFYN'S method, II, 114, 286; artificial anus, II, 109, 113; operation to produce artificial anus, II, 84; prolapsus of, II, 254.

Aorta, aneurism of, II, 189; ball encysted between aorta and vena cava, II, 135; wounds of, I, 519; ecchymosis of arch of, I, 572; exposed to view in shot wound of chest, I, 487, 597; hæmorrhage from descending, III, 764.

Aphonia in shot wounds of cranium, I, 47, 108, 266, 283, 338, 382; voice restored after hæmorrhage from fauces, I, 46; restored during vomiting, I, 635.

Apparatus, for excisions of head of humerus, II, 568, 563, 580, 594; for excisions in shaft of humerus, II, 675; for excisions at elbow, II, 849, 907, 908; for double amputation of forearm, II, 968; for dangle wrist, II, 1015; for amputation at the hip, III, 131, 162; for excision in shaft of femur, III, 202; for amputation of both thighs, III, 224; for fractures of femur, III, 343–349.

Arachnitis after bayonet wound of cranium, I, 32; after shot wounds of cranium, I, 53, 113, 125, 298.

Arm, shot injuries of, II, 807–815; carried away by missile, II, 620, 622, 623, 625, 628, 629, 631, 632, 633, 634, 636; amputation of, for shot flesh wounds, II, 469, 470; amputations of, for shot fractures, II, 697; primary amputations of, II, 697–750; autopsies, II, 717, 736, 748; intermediary, II, 752–775; autopsy, II, 772; secondary, II, 775–792; autopsy, II, 781; mortality of amputations of, II, 805–807, 824; large mortality in amputations in lower third, II, 824; ages of patients in amputations of, II, 806; amputations of arm in eastern and western armies, II, 807.

Arnold's ambulance wagon, III, 951.

Arrow Wounds, of cranium, I, 34; penetrating abdomen, II, 33; of bladder, II, 276; of knee joint, III, 653.

Arteries, statistics of wounds of, III, 763; frequency of hæmorrhages from, III, 763; erysipelas, gangrene, pyæmia, and tetanus in injuries of, III, 763; primary injuries of, II, 621, 622, 625, 626, 627; III, 763–765; primary hæmorrhages in wounds of, III, 763, 764, 765; enlargement of arteries, III, 667; ossification of, III, 652; torsion of, II, 842; atheroma of, III, 810; ligation of, to control inflammation, III, 377, 383; transportation in cases of wounded arteries, III, 810; occlusion of, by impacted ball, III, 756; ligations of, III, 765. See the several arteries, **Aorta,** etc.

Arteriotomy in concussion of brain, I, 37.

Arthritis, traumatic, I, 116; II, 490, 493; III, 27, 28, 54, 287, 290, 552.

Articular Arteries of popliteal: hæmorrhages, III, 764; ligations, III, 765; primary injury of, III, 764.

Artificial pupil, operations for, III, 681, 682.

Ascites, paracentesis abdominis in cases of, II, 191; in wound of bladder, II, 273.

Asphyxia, in wounds of face, I, 350; of neck, I, 417, 418, 419; of chest, I, 516; of spine, I, 427, 452.

Astragalus, excisions of, III, 585, 587, 588, 591, 595, 624.

Atheroma of arteries, III, 810.

Auricular Artery, hæmorrhages from, I, 101, 224, 393; III, 763; ligations of, I, 238; III, 765, 771; primary injury of, III, 763; primary hæmorrhage from, III, 763.

Axillary Artery, aneurisms, I, 528, 539, 541, 542, 543, 545; II, 443, 455, 468, 572, 650; III, 808; wounds of, I, 538, 539, 553; II, 443, 454; III, 764; primary hæmorrhages of, III, 764; ligations of, I, 553, 556; II, 442, 444, 468, 642–644, 647, 780; III, 511, 662, 679, 765; summary of cases, III, 775; limits of, II, 444; days intervening between injury and hæmorrhage, II, 442.

Axillary Pad, STROMEYER'S, II, 517.

Axillary Vein, wounds of, I, 539, 542, 555; II, 640; ligations of, I, 539, 555.

Back, bayonet wound of, I, 356; II, 429; III, 686; incised wound of, III, 653; punctured wounds of, II, 429; shot flesh wounds of, II, 427, 428, 429–432; III, 689; gangrene in wounds of, II, 432.

Balls, varieties of, III, 697; with guiding attachment, III, 700; balls lodged in brain, I, 251, 252, 255, 258; in face, I, 316; in ilium, II, 216, 222; in bladder, II, 271, 272, 273, 286; innocuously in knee joint over fifteen years, III, 372; between innominata and vena cava, I, 534; against innominata, I, 521; embedded in parotid gland, I, 305; concealed under petrous bone, I, 367; held in folds of omentum, II, 147; ball encysted: in brain, I, 204, 302; near lung, I, 587; between vena cava and aorta, II, 135; in mesenteric pouch, II, 179; in thigh, II, 100, 425; in penis, II, 345; ball pressing on nerve, I, 410; balls extracted, I, 309, 316; II, 11, 12, 218, 235, 283; by trephine, I, 366; balls ejected in coughing, I, 329, 342, 464, 465, 431, 596, 598, 629; ball ulcerating into cavity of lung, I, 493; ball inverting in wound, I, 532; II, 619; acting as plug in injured blood-vessels, III, 756; balls voided at stool, I, 515, 584, 598; II, 36, 37, 70, 99–101; erratic course of, II, 134, 368, 487; brush of, III, 706, 707; windage of, I, 344, 385; III, 706, 707; ball flattened by contact with bone, III, 717; balls split: on cranium, I, 180–182; on bones of face, I, 338; on bones of chest, I, 563, 570, 577, 593; on ilium, II, 232; on tibia, III, 717, 718. See **Conoidal Balls, Musket Balls, Explosive Balls, Missiles.**

Bandaging, results of injudicious, II, 513, 517; III, 867. SEUTIN'S starch bandage, III, 620.

Battles and Engagements, chronological summary of, I, xxiii–clv.

Bayonet Wounds, III, 685, 686, 687; relative percentage of, to sabre and shot wounds, III, 685, 687; of scalp, I, 30, 31; of cranium, I, 31–34; of face, I, 323, 324; of neck, I, 400; of chest, I, 467, 470, 599; of heart, I, 468; of abdomen, II, 3, 4, 31, 32, 323, 335; of flesh wounds of lower extremities, III, 5, 6; of knee joint, III, 360; of foot, III, 617.

Bed-cards, form of, I, xviii.

Bile, extravasation of, II, 192, 193; escape of, in shot wounds of liver, II, 142, 143.

Bladder, injuries of, II, 262–303; ruptures of, II, 263; punctured, incised, and lacerated wounds of, II, 263; arrow wound of, II, 276; concussions of, II, 264; shot wounds of, II, 264; frequency and fatality, II, 264; III, 689; diagnosis and treatment, 301, 302; opium, 303; autopsies, II, 288, 291, 292, 293, 295, 296; foreign bodies in, II, 268; autopsy, II, 425; clothing removed from, II, 280; bone removed from, II, 277, 278, 279; missiles removed from, II, 270–281; puncture of, II, 365, 370, 381, 385. See **Lithotomy.**

Bleeding from injured artery arrested by lodgement of ball, III, 756; primary, III, 763, 764.

Blepharoplasty, I, 368.

Blood, extravasation of: in contusions of cranium, I, 63, 112; in fractures of cranium, I, 67; in brain, I, 332; in abdomen, II, 189, 190, 191; in pelvic cavity, II, 220; transfusion of, II, 642; III, 811.

Blood-vessels, injuries of, by round ball, III, 750; by conoidal ball, III, 750; by fragments of shell, III, 756; by spiculæ of bone, III, 755, 756; shot contusions of, III, 755; complete division of, III, 752; partial division of, III, 754; retraction after injury of, III, 752, 754; primary injury of, III, 763, 764; primary bleedings from, III, 763, 764; of abdomen, II, 24, 174, 175, 202; III, 689; of chest, I, 650; ligation of, I, 521, 525. See **Arteries, Veins.**

Bone, early removal of fragments of, I, 598; II, 235; III, 416, 867; union of, III, 203, 208, 211, 212; formation of new, III, 182, 223; wiring of, II, 819, 820; III, 212; drilled to facilitate formation of callus, III, 659; osteitis in contusions of, II, 818; fragments of, removed from bladder, II, 277, 278, 279.

Bone Forceps, II, 256, and plate opposite.

Bougies, II, 405.

Brachial Artery, aneurisms of, II, 444, 463, 468, 470; III, 680, 808; incised wound of, III, 680; punctured wound of, II, 436; shot injuries of, I, 553; II, 445, 455, 627, 674; III, 764; primary hæmorrhages from, III, 764, 765; obliteration of, II, 467; ligations of, I, 553; II, 446, 650, 760, 763, 764, 769, 773, 774, 785, 840, 843, 926, 955, 958, 959, 986, 1010; III, 663, 680; summary of cases, III, 765, 777–782.

Brachial plexus of nerves, wounds of, I, 409, 410, 461, 462.

Brachial Vein, hæmorrhages from, III, 816; wounds of, II, 436; ligations of, II, 436, 446, 448.

Brain, shot concussion of, I, 37, 65–67; treatment by cannabis indica, 109, 113, 118, 121, 122, 125, 308; compression of, after shot wounds, I, 18, 21, 38, 67, 126; after miscellaneous injuries, III, 640; loss of substance of, I, 208, 210, 218, 235, 241, 242, 257, 260; laceration of, I, 37, 39, 40, 67; pus in, I, 126; inflammation of, I, 111; exposure of, I, 46, 133, 162, 170, 199; ball encysted in, I, 204, 302. See **Cerebral Hernia.**

Bromine in cases of gangrene, III, 292, 834.

Buccal Cavity, shot wounds of, I, 392.

Buck and Ball, III, 700; injuries by, III, 710, 714.

Burns and Scalds, III, 641.

Bushe's Compressor for hæmorrhage in rectum, II, 320.

Buttocks, flesh wounds of, II, 428.

Cacolets, III, 926–931; cacolets of: KOHLER; PROAL; LAWRENCE, BRADLEY & PARDEE; DAVIS; WOODCOCK; JONES; SPENCER, NICHOLS & CO., and POMEROY & CO.

Calcaneum, injuries of, see **Os calcis.**

Calculi, vesical, II, 269–283; around foreign bodies, II, 298; formed on projectiles, II, 271, 272, 273, 274, 275, 276; on hair, II, 281; passed by urethra, II, 376; instruments for crushing, II, 378–379; renal, III, 540.

Canister-shot, nature of injuries by, III, 696, 706; description of, III, 697.

Cannabis Indica in cerebral disturbances, I, 58.

Carditis in shot wounds of chest, I, 622.

Caries in shot contusions cranial bones, I, 106, 128.

Carotid Artery, aneurisms of, I, 355; II, 499, 500; III, 679, 808; wounds of *common*, I, 350, 352, 353, 412, 416, 420, 421; II, 500; III, 679, 751; of *external*, I, 347, 421; of *internal*, I, 432, 456; occlusion of common, by impacted ball, III, 756; rupture of common, during coughing, I, 350; hæmorrhages from, III, 763; ligations of common, I, 421; III, 766, 767–770; disadvantages of ANEL'S operation, I, 423; ligation of external, III, 765, 770.

Casualties among army surgeons, I, xxx–xxxii.

Cataract, traumatic, I, 193, 340, 345; operation for, III, 681.

Catheters, II, 380–384; of SQUIRE, II, 392; of GAUJOT and SPILLMAN, II, 381; catheter found at Pompeii, II, 382; curved gum-elastic, II, 382; of HEISTER, II, 382; of BOYER, II, 386; catheter gouge, II, 384; unsuccessful attempts to introduce, II, 352, 365, 370, 373; broken in dilating stricture, II, 376; broken in wound, II, 379; use of, causing fistulas, II, 363; essential in wounds of urethra, II, 351, 354; in wounds of penis, II, 348.

Cerebral Artery, hæmorrhage from, I, 269; III, 764.

Cerebral Hernia, after sabre fractures, I, 27; after bayonet fractures, I, 32; after miscellaneous injuries, I, 44, 58, 60; after shot contusions cranial bones, I, 123; after shot fractures cranium, I, 206, 210, 211, 212, 249, 260; excisions of, I, 294–298, 302, 303; summary of operations, I, 309, 317, 318.

Cervical Artery, Superficial, hæmorrhage from, III, 764; ligations, III, 765, 774.

Cervical plexus of nerves, wound of, I, 405.

Cheek, shot wounds of, I, 387.

Cheiloplasty, I, 374.

Chest, injuries of, 465–650; frequency of, I, 509, 600, 602, 603; mortality in, I, 604–611. *Miscellaneous injuries* of, I, 466; punctured wounds of, I, 599; incised wounds of, I, 470, 471, 534, 599; incised wound of sternum, I, 534. *Sabre wounds* of, I, 466, 471, 599; III, 686. *Bayonet wounds* of, I, 467, 470, 599; autopsy, I, 468. *Contused wounds* of, I, 471, 599. *Shot wounds* of, I, 472–650; III, 689; shot flesh wounds of, I, 472, 473, 599; III, 689; shot penetrations of, I, 599, 600, 606; perforations of, I, 606; fractures without penetrations of, I, 473, 474–476; autopsies, I, 474, 475, 476; internal without external injuries of, I, 476, 477; penetrations of, without fracture, I, 478–482; penetrations of, with fracture, I, 482–495; with fracture of scapula, I, 483, 484, 486, etc.; of ribs, I, 482, 484, 485, etc.; of clavicle, I, 482, 484, etc.; of sternum I, 486, 488, etc.; penetrations involving lung, I, 492–497, 634; hermetical sealing, I, 497–514; involving blood-vessels, I, 519–528; pericardium and heart, I, 528–530; mediastinum, I, 486, 530, 535, 589; thoracic duct, I, 535; lodgement of missiles in, I, 606, 617; hæmorrhage in wounds of, I, 611; complications in wounds of, I, 472, 631, 633, 634–638; treatment of wounds of, I, 642; operations on, 537.

Chisolm's Inhaler, III, 889.

Chloroform, percentage of surgical operations in which it was used, III, 887; value and efficiency of, III, 888; deaths from, III, 890–894; HALL'S method of artificial respiration, II, 242; quantities required to induce anæsthesia, III, 896; period during which it was maintained, III, 896; vomiting, excitement, prostration after administration of, III, 897; use of stimulants prior to administration of, III, 889; larynx opened to restore life after administration of, II, 841.

Chloroform and Ether, III, 888; deaths from, III, 894; time to induce anæsthesia, III, 896; period during which it was maintained, III, 896; vomiting and excitement after administration of, III, 897.

Circumcision for phimosis, II, 361, 374.

Circumflex Artery, of axillary, aneurism of, III, 808; incised wound of, II, 498; shot wound of, II, 557; III, 764; ligations of, I, 557; II, 454, 468, 498, 525, 551, 590, 605, 629, 649, 682; III, 765, 777; circumflex of femoral, hæmorrhage from, III, 764; circumflex of iliac, II, 324; III, 764.

Civiale's Lithotrite, II, 378.

Clavicle, sabre fractures of, II, 474; III, 686; bayonet fractures of, II, 474; III, 686; shot fractures of, II, 474; III, 690, 870; autopsies, II, 491; excisions in, I, 557–562, 598; II, 477, 489, 497–499; III, 870; simple fracture of, from fall, I, 562.

Climate, effects of, on treatment of wounds, III, 867, 868.

Coccyx, shot fractures of, II, 252; treatment, II, 253.

Colica Media Artery, hæmorrhage from, III, 764; wound of, II, 69.

Colon, punctured wounds of, II, 76; incised wounds of, II, 76; shot wounds of, II, 77–105, 153, 179, 288, 309, 318, 331.

Compression, for hæmorrhage, II, 9, 10, 320, 922, 932; III, 515, 537, 569, 810; in wounds of abdominal parietes, II, 9, 10; in scalp wounds, I, 16.

Compressor, BUSHE'S, for hæmorrhage in rectum, II, 320.

Confederate hospital records, I, xx.

Conoidal Balls, injuries by, III, 696; effectiveness of, III, 709; range of, III, 709; appearance of injuries by, III, 711; varieties of, III, 697; power of penetration, III, 757.

Contre-Coup, I, 214, 304, 305, 306.

Contusions, shot, of bone, III, 716; of blood-vessels, III, 755.

Contusions and Sprains, III, 642.

Coxitis, traumatic, III, 9, 25, 26, 27.

Cranium, *sabre fractures* of, I, 16–28; of frontal bone, I, 16, 18, 19, 20, 21, 22; of occipital, I, 17, 18, 20, 21, 23; of parietal, I, 16, 17, 18, 19, 20, 21, 22, 23; of temporal, I, 21, 23; of sphenoid, I, 33; exfoliation of cranial bones after sabre fractures of, I, 17, 20, 21, 24; necrosis of, I, 18, 21; trephining after sabre fractures of, I, 17, 22, 23, 24; pyæmia after sabre fractures, III, 687. *Bayonet fractures* of, I, 31–34, 308; of frontal, I, 32, 33; of parietal, 31, 32, 33; treatment of bayonet fractures of, I, 34. *Sabre and bayonet fractures* of, III, 686, 687. *Miscellaneous injuries* of: railroad accidents, falls, blows, falling trees, kicks, I, 35–69, 305, 308; fracture external table only, I, 54, 55, 68; bone removed, I, 55, 57, 69; trephining of cranial bones, I, 57–60, 69; III, 657. *Shot contusions:* frontal, parietal, temporal, and occipital bones, I, 95–128, 308; III, 688; exfoliation of, after shot contusions, I, 102, 103–106, 114, 119, 122, 123, 127; removal of exfoliation, I, 103, 104, 105, 114; trephining for shot contusions of, I, 122–126; balls lodged in, I, 96, 101, 102, 103, 105, 109; balls removed from, I, 97, 101, 102, 103, 105, 109. *Shot fractures of external table alone*, I, 128–141, 307; III, 688; of temporal bone, I, 131, 132, 136, 137; frontal, I, 128–139; of occipital, I, 134, 135, 138, 139; of parietal, I, 132, 133, 134, 137, 138; exfoliation removed, I, 132; bone removed, I, 129, 130, 134, 135; ball lodged in, I, 130, 131, 136; ball removed from, I, 130, 131, 136. *Shot fractures, inner table alone*, I, 141–159, 307, III, 688; trephining for shot fractures of inner table, I, 148, 149. *Shot fractures of both tables*, I, 159–214; linear or capillary fissure, I, 159–160; autopsies, I, 159–160; III, 688. *Shot fractures of both tables, without depression*, I, 161–167; III, 688; numerical statement of cases of, I, 307; mortality of, I, 307. *Shot fractures of both tables, with depression*, I, 167–190; III, 688; balls splitting on the cranial bones, I, 180–182; balls lodged, I, 169, 179, 180, 182, 184; balls removed from, I, 168, 170, 175, 177, 178, 181, 183, 190; numerical statement, I, 307. *Shot penetrating fractures*, I, 190–206, 307; III, 688; balls lodged within the cranial cavity, I, 191, 192, 193–196, 200, 201, 202, 203, 204, 205, 206; missiles extracted from within the cranium, I, 191, 196–200, 201, 203; exfoliations, I, 192, 196. *Shot perforations*, I, 206–212, 307; III, 688; exfoliations after shot perforations, I, 208; ecrasement, crash or smash, I, 213–214, 307; III, 688. *Removal of fragments*, I, 215–261; lodgement of foreign bodies, I, 236, 237, 251; exfoliations, I, 215, 223, 227, 228, 231, 240. *Trephining after shot fractures*, I, 261–293, 299, 316, 317, 319, 320. *Contre-coup*, I, 304, 306, 307; III, 688. *Tabular statement of operations on cranium*, I, 309.

Crural Nerve, shot wounds of, I, 446; II, 400; III, 9, 74, 823.

Cuboid Bone, excision of, III, 625, 626, 627.

Cuneiform Bone, excision of, III, 623, 626, 627.

Cutaneous Nerve, *external*, injury of, II, 464, 470; excision of, II, 470; *internal*, wound of, II, 462, 463, 928; excision of, II, 462.

Cystitis, II, 221, 238, 239, 267, 287, 309, 356, 370.

Deglutition, difficulty of, in shot wounds of neck, I, 403, 405, 411, 413; in shot wounds of cranium, I, 263.

Dental Artery, hæmorrhage from, I, 346, 353.

Diaphragm, bayonet wounds of, I, 467, 469; punctured wound of, II, 76; shot wounds, I, 536, 606, 634; ball lodged in, I, 480; rupture of, without external wound, II, 25; hernia of, I, 515, 516.

Diastasis of cranial bones, I, 213.

Digital Arteries, injuries of, II, 459; III, 764; ligations of, II, 454; III, 765, 785, 786.

Dilatation, in strictures of urethra, II, 388; instruments for, by PERRÈVE, II, 387; by SHEPPARD, II, 388; by WAKLEY, II, 388; by MALLEZ, II, 389; by MICHELÉNA, II, 389; by RIGAUD, II, 389; by MATHIEU, II, 389; by SÉGALAS, II, 390; by HOLT, II, 390; by VOILLEMIER, II, 390; by GOULEY, II, 390, 391; by DUCAMP, II, 391; by TEEVAN, II, 391.

Diphtheria, operations for, I, 418.

Dislocations, following shot wounds: at the hip, III, 67, 68, 69, 70, 71, 76, 83; at the knee, III, 373; of patella, III, 273; after excisions of bones of leg, III, 446, 447; for miscellaneous injuries, III, 644.

Division Hospital, personnel of, III, 902; duties of recorder of, III, 909.

Dorsalis Carpi Artery, hæmorrhage from, III, 764; ligations of, III, 765, 785, 786.

Dorsalis et Rad. Ind. Artery, III, 764; ligations of, III, 765, 785, 786.

Dorsalis Pedis Artery, hæmorrhage from, III, 53, 764; ligations of, III, 621, 765, 803.

Double Amputations for shot wounds, III, 880; mortality, III, 881.

Drainage Tubes, in cases of empyema, I, 580; SMITH'S watch-spring dilator for sinuses, I, 580.

Drowning, summary of cases of, III, 641.

Dry Gangrene, II, 351; III, 850, 851; after ligation of ulnar artery, II, 436; after shot wounds, II, 351; III, 310, 314, 542; for frostbite, III, 678; due to impaired circulation, III, 850.

Duodenum, shot wounds of, II, 67, 68, 134, 147.

Dyspnœa, in wounds of chest, I, 638; in wounds of spine, I, 432, 434, 449, 454.

Ear, wounds of, I. 384; rupture of membrane of, by explosion, I, 385; total loss of, I, 387.

Ecchymosis, Lumbar, as a sign of penetrating wound of chest, I, 575.

Ectropion, operation for, III, 683.

Effusions, SMITH'S apparatus for, in plural cavity, I, 627.

Elbow Joint, wounds and injuries of, II, 827; *bayonet* wounds of, II, 827; III, 686; *sabre* wounds of, II, 827; III, 686; *shot* wounds of, II, 828; III, 690; shot fractures of, in Confederate army, III, 690; shot fractures of, treated by *conservation*, II, 830, 915; III, 870; autopsies, II, 841, 843, 844; *excisions* at, II, 845; III, 870; primary excisions, II, 845; intermediary excisions, II, 864; secondary excisions, II, 884; *excisions* at, followed by *amputation*, III, 870, 871; excisions at, for miscellaneous injuries, III, 657, 658; excisions at, in Confederate service, II, 896, 897, 899, 900; extent of bone removed in excisions at, II, 906; mode of operation, II, 906. Splints used in fractures of: ESMARCH'S, II, 825, 888; AHL'S, II, 888; BOND'S, II, 897; HEATH'S, II, 905; HODGEN'S wire suspension, II, 904; VOLKMANN'S wire splint, II, 904; BAUER'S, II, 835. Apparatus for excision at: HUDSON'S, II, 907; LANGENBECK'S, II, 907; SOCIN'S, II, 907; *amputations* at, II, 909; III, 871; primary disarticulations at, II, 910; intermediary, II, 912; secondary, II, 913; mortality of amputations at, II, 909; dislocation at, II, 827, 837.

Electricity applied to wounded nerves, I, 387, 409; II, 1020; III, 9.

Emphysema in wounds of the neck, I, 415; of the chest, I, 493, 579, 590, 613-15; II, 145, 160.

Empyema in wounds of the chest, I, 470, 472, 490, 529, 578, 627; II, 290.

Encephalitis, in shot contusions of cranial bones, I, 111, 112; in fractures of cranium, I, 205, 257.

Endocarditis, I, 533.

Enterorrhaphy, II, 112, 124, 128; methods of, PALFYN, II, 114; LAPEYRONIE, II, 115; REYBARD, II, 115; LE DRAN, II, 115; the four masters, II, 116; DENANS, II, 116; RAMDOHR, II, 117; JOBERT, II, 118; LEMBERT, II, 119; GÉLY, II, 119; EMMERT, II, 121; BAUDENS, II, 122; SPILLMANN, II, 122; VÉZIEN, II, 121; BOUISSON, II, 122; BÉRANGER-FÉRAUD, II, 122; advocated by LARREY, BAUDENS, PIROGOFF, LOHMEYER, etc., II, 124-126; opposed by F. H. HAMILTON, etc., II, 124.

Entrance and Exit Wounds, II, 258; III, 711.

Entropion, operations for, III, 681, 682.

Epididymitis, II, 248.

Epigastric Artery, wounds of, II, 175; hæmorrhage from, II, 9, 103, 178; III, 764; *ligation* of, II, 186; III, 40; ligation of superficial epigastric, III, 40.

Epilepsy in shot wounds of cranium, I, 118, 119, 176, 177, 229.

Erysipelas, *traumatic*, in scalp wounds, I, 77, 78, 79, 82; in wounds of the face, III, 852; in wounds of neck, I, 402, 404, 408, 412, 413; in shot wounds of upper extremities, III, 852; in wounds of chest, I, 634; of the back, II, 432; in flesh wounds of lower extremities, III, 37; in fractures of thigh, III, 352; of the knee joint, III, 408, 416; in shot wounds of the lower extremities, III, 852; frequency of, III, 851, 852; fatality, III, 854; regional frequency, III, 852; duration of, III, 852; repeated attacks of, III, 853; causes of, III, 855, 856; treatment of, III, 855; following excisions, III, 857; following amputation, III, 857; among white and colored troops, III, 857; *idiopathic*, III, 676.

Ether, in major operations, III, 887, 897; deaths from, III, 894, 895; autopsies in cases of death from, III, 894, 895, 898.

Excisions of the bones of the head, see **Trephining;** of the bones of the face, I, 383, 398; of portions of the spine, I, 463, see **Vertebræ;** of the bones of the chest, I, 557, 598, 616, see **Clavicle, Ribs, Scapula, Sternum;** of pelvic bones, II, 255; in the extremities, III, 874–876; for specific operations see parts excised.

Excitement during anæsthesia, III, 897.

Execution of Sentence, III, 641.

Explosive Balls, I, 494; II, 923; III, 24, 176; injuries by, III, 696, 701, 702–704.

Extirpation of eye, for shot injury, I, 199, 217, 330, 345; for miscellaneous injuries or diseases, III, 681, 683.

Extravasation of blood in shot contusions of head, I, 38, 63, 67, 110, 112, 120, 125; in fractures of cranium, I, 332; in wounds of abdomen and pelvic cavity, II, 176, 177, 194, 220; of fæcal matter, in wounds of stomach, II, 42, 48, 57; of bile, II, 192, 193; of urine, II, 193; incisions for, II, 206.

Extremities, shot flesh wound of, 873; *shot fractures* of, III, 873; treated by *conservation*, III, 869–874; by *excision*, III, 869, 870, 871, 872, 874–876; by *amputation*, III, 869, 871, 872, 877–886; by *excision* and subsequent *amputation*, III, 869, 870, 871; by *amputation* and *re-amputation*, III, 869, 870, 871; *upper extremities*, punctured flesh wounds of, II, 435; sabre and bayonet wounds of, III, 686; shot flesh wounds of, II, 435; III, 690, 870, 871; mortality, III, 690; gangrene in wounds of, III, 824; erysipelas, III, 852; pyæmia, III, 859; tetanus, III, 819; excisions in, III, 870, 871; amputations in, III, 870, 871; *lower extremities*, punctured flesh wounds of, III, 5; sabre and bayonet wounds of, III. 686; shot flesh wounds of, III, 690, 870, 871; shot fractures of, III, 690; fatality, III, 690; complications in shot wounds of: gangrene, III, 824; erysipelas, III, 852; pyæmia, III, 858; tetanus, III, 819; amputations for miscellaneous injuries in, III, 664.

Eye, punctured wound of, I, 386; shot wounds of, I, 325; destruction of both, I, 325, 342, 343, 345; destruction of one eye, I, 329, 343; balls lodged in orbit, I, 340, 342; should be extracted, I, 345, 385; incisions in ophthalmitis, I, 345; extirpation of eye, I, 199, 217, 330, 345; artificial eyes, I, 345, 387; operations for miscellaneous injuries and diseases of, III, 681.

Eyelid, excision of tumor of, III, 682.

Face, injuries of, I, 321–398; mortality, I, 382; miscellaneous injuries of, I, 324; punctured wounds of, I, 324; incised wounds of, I, 324; lacerated wounds of, I, 324; sabre wounds of, I, 321–323; III, 686; bayonet wounds of, I, 323, 324; III, 686; shot wounds of, I, 325–398; III, 688; fatality of shot wounds of, I, 325; shot flesh wounds of, I, 383; III, 688; shot contusions of, III, 324; shot fractures of, I, 381; III, 688; balls extracted, I, 383; removal of fragments, I, 383; excisions of bones of, I, 383, 398; complications in shot wounds of: gangrene, III, 824; erysipelas, III, 852; pyæmia, III, 859; tetanus, III, 819; plastic operations III, 369, 380–383.

Facial Artery, shot wounds of, I, 350, 353, 397, 420; hæmorrhage from, I, 346, 348; ligations of, I, 374, 422; III, 765, 772; ligation of, for incised wound, III, 656.

Facial Nerve, wounds of, I, 387; treatment of, by electric currents, I, 387

Fæcal Fistula, II, 24, 49, 113, 252, 253, 277; plastic operation for, II, 79, 84, 85.

Fæces, extravasation of, II, 61, 77–97, 194, 195; fæces vomited in shot wounds of intestines, II, 79, 184, 189; involuntary evacuation of: in fractures of cranium, I, 19, 45, 124, 146; in wounds of spine, I, 431, 432, 461, 462.

Faradization, II, 342; III, 9.

Femoral Artery, aneurisms of, III, 808; bayonet wound of, III, 6; incised wound of, III, 197; shot wounds of, III, 135, 160, 764; shot perforation of, III, 755; hæmorrhages of, III, 764; primary bleedings of, III, 764; obliteration of, III, 45, 56; occlusion of, III, 13; emboli in, III, 14, 191; ligations of, III, 765, 788, 789, 798.

Femoral Vein, shot injuries of, III, 43, 44; partial division of, III, 754; hæmorrhages from, III, 757, 816; primary bleedings of, III, 762; ligations of, III, 44, 47, 48, 49, 56; thrombi in, III, 79, 191, 590; removal of darning needle from sheath of, III, 43.

Femur, shot contusions of, III, 169, 716; amputations in cases of, III, 172; shot fractures of, III, 174; shot fractures treated by conservation, III, 176: in upper third, III, 177; in middle third, III, 187; in lower third, III, 194; partial shot fractures of, III, 175; perforations of, III, 721; simple shot fractures of, III, 705; pseudarthrosis after fractures of, III, 174, 175, 176, 198, 199; extension and counter-extension in fractures of, III, 343; side fractured, III, 352; complications of fractures of: pyæmia, III, 352; tetanus, III, 352; gangrene, III, 352; erysipelas, III, 352; hæmorrhage, III, 352; lengthening and shortening of, III, 351; eversion of foot in fractures of, III, 180, 195, 198, 199; inversion of foot, III, 187; treatment of fractures of, III, 338; mortality in Union and Confederate armies, III, 355; splints and apparatus for fractured, III, 342: DESAULT'S, III, 343; SMITH'S anterior, III, 345, 346; HODGEN'S, III, 346, 347, 348; SWINBURNE'S, III, 347; PHYSICK'S, III, 343; GURDON BUCK'S, III, 348; LANGER'S, III, 349; BELL'S double-inclined plane, III, 345; HUDSON'S, III, 180; HOWARD'S wire suture, III, 350, 351; fracture of, treated by *excision*, III, 199; primary excisions, III, 200; intermediary excisions, III, 207; secondary excisions, III, 210; results of excisions discouraging, III, 199; excisions for miscellaneous injuries, III, 657; amputations in femur, see **Thigh.**

Fibula, shot fractures of, III, 432, 564; treated by conservation, III, 437; excisions of, III, 445; fractured by patient's weight after excision of tibia, III, 464, 480.

Field Companion, surgeon's, III, 915.

Field Hospitals, III, 920–922.

Field Register, form of, I, xiv.

Fingers, amputations of, for shot injury, II, 1019; for miscellaneous injuries, III, 659.

Fire-balls, III, 701.

Firearms, rifled, superiority of, over smooth-bore, III, 694; firearms used during the war, III, 695–704.

Fistula, anal, II, 321; gastric, II, 45–48; case of Alexis St. Martin, II, 55; thoracic, I, 630, 479, 480, 488, 490, 502, 577; urethral, II, 360–371; non-traumatic urinary, II, 368, 387, 400; traumatic urinary, II, 403; recto-vesical, II, 309, 310, 313; lachrymal, I, 329, 358; salivary, I, 330, 368, 387.

Foot, bayonet wounds of, III, 617; shot wounds of, III, 617; shot contusions of, III, 617, 690, 716, 870; shot fractures of, III, 618, 690, 870; treated by expectation, III, 618; treated by *excision*, III, 622, 627, 637, 638; primary, III, 623; intermediary, III, 624; secondary, III, 625; excisions in bones of foot for miscellaneous injuries, III, 657; *amputations* of, III, 627; primary, III, 628; intermediary, III, 633; secondary, III, 634; CHOPART'S operation, III, 639; LISFRANC'S, III, 639, HEY'S, III, 639.

Forearm, II, 917; punctured and incised wounds of, II, 918; sabre wounds of, II, 918; III, 686; shot wounds of, II, 919; III, 690, 870; shot flesh wounds of, II, 917; amputations following shot flesh wounds of, II, 471; shot contusions of, II, 919; III, 716; partial shot fractures of, II, 921; shot fractures of, treated by *expectation*, II, 922; III, 870; mode of treatment, II, 992; splints for shot fractures of: HEWIT'S, II, 932; SWIFT'S, II, 932; VEDDER'S, II, 932; carried away by shot, II, 625, 626, 647; *excisions* in, for shot injury, II, 933, 966; III, 870; primary, II, 933; intermediary, II, 953; secondary, II, 961; amputations following excisions in, III, 870, 871; *amputations* for shot injuries of, II, 967, 993; III, 871; primary, II, 967; intermediary, II, 980; secondary, II, 987; re-amputations in, III, 870, 871; amputations for miscellaneous injuries, III, 659, 662; apparatus for double amputation of forearm, II, 968.

Foreign Bodies, lodged in chest, I, 582, 584, 590, 598, 617; extracted from chest, I, 590–593, 595, 598; removed from abdominal parietes, II, 11, 12, 89, 90, 93, 146, 148; removed from flesh wounds, lower extremities, III, 21, 22; removed from stomach, II, 52; early removal of, advised, III, 867; removed from bladder by lithotomy: clothing, II, 280; hair, II, 281; arrow-head, II, 276; bone, II, 277–279; portion of bayonet scabbard and of bayonet extracted by incision in perinæum, II, 245; lodgement of foreign bodies, III, 758.

Fougasses, III, 699.

Fracture-bed, LANGER'S, III, 349; PETIT'S, III, 568.

Fractures, simple shot, III, 704, 705; of humerus, II, 815, 816; of femur, III, 705; without fissuring, III, 719; with fissuring, III, 720; perforating, III, 721.

Frontal Artery, hæmorrhage from, I, 81; III, 763.

Frostbite, III, 671; amputations for, III, 671, 672, 673, 674, 675, 676, 677.

Gall-bladder, shot wounds of, II, 136, 137, 140; shot rupture of, II, 195

Galvanism to revive patient asphyxiated by ether, II, 187.

Gangrene, frequency of, III, 824; fatality and causes of death, III, 824; frequency of, after excisions, III, 825; after amputations, III, 825; influence of season on, III, 825; years in which the disease occurred, III, 815; at Frederick, III, 826; at West Philadelphia, III, 826; at Annapolis, III, 830; symptoms of, III, 827; contagion by, III, 826, 827, 848; microscopical appearance of, III, 830; characteristics of, III, 827, 828, 836, 840; treatment of, III, 826–830; treatment by bromine, III, 834–837; following strangulation by tourniquet, III, 825; caused by tight bandaging, III, 825; in scalp wounds, I, 79, 89; in wounds of the face, III, 824; in wounds of spine, II, 169; in chest wounds, I, 472, 634, in wounds of abdomen, II, 8, 10, 12; in wounds of back, II, 432; in wounds of upper extremities, III, 824; in wounds of lower extremities, III, 352, 569, 824; hæmorrhage in cases of, III, 763, 764; senile, III, 675. See **Dry Gangrene.**

Gases in penetrating wounds of stomach, II, 198.

Gastric Artery, branches of, severed in shot wound of pancreas, II, 160.

Gastric Fistula in shot wounds of stomach, II, 45–48, 50, 52, 53, 54, 56; case of Alexis St. Martin, II, 55.

Gastro-epiploic Artery, bayonet wound of branch of, ligated, II, 42.

Gastroraphy, II, 58, 59, 113.

Genioplasty, I, 375.

Genital Organs, injuries of, II, 343; shot wounds of, III, 689; operations on, for miscellaneous injuries, III, 684. See **Penis, Urethra, Testes, Scrotum.**

Glands, inflammation of prostate, III, 81; enlargement of inguinal, III, 225; ball embedded in parotid, I, 305; wound of parotid, I, 406, 411.

Glottis, œdema of, I, 404, 417, 418.

Gluteal Artery, wounds of, II, 328, 330, 331, 334; cut during operation, III, 97; hæmorrhages from, II, 327, 328, 329, 330; III, 764; ligations of, II, 329, 330, 332; III, 97, 765, 787.

Gluteal Vein, injuries of, II, 338; III, 816.

Grape-shot, description of, III, 697; nature of injury by, III, 706; parts injured by, III, 696.

Greek Fire, III, 701.

Hæmatemesis, in rupture of stomach without external wound, II, 22; in wounds of stomach, II, 41, 42, 47, 57; in wounds of intestines, II, 67, 88; in wounds of neck, I, 403, 413; of spine, I, 445.

Hæmatocele, II, 364.

Hæmaturia, II, 167, 168, 169, 179, 284, 290, 294, 335.

Hæmoptysis, not a certain sign of wound of lung, I, 636; cases, I, 482, 507; I, 145, 146.

Hæmorrhage, *arterial*, summary of cases of, III, 763; fatality of, III, 765; days on which first hæmorrhage occurred, III, 805; long deferred, III, 806; recurrent, III, 806; warning bleedings, III, 807; from distal ends of arteries, III, 807; capillary, III, 807; parenchymatous, III, 193, 807; medullary, III, 808; treated by compression and styptics, III, 810, 811; by ligation, III, 810; by ligation and subsequent amputation, III, 810; acupressure in, III, 811; actual cautery in, III, 811; treated by application of ice and cold, III, 813; primary hæmorrhage, III, 761, 763, 764; after complete divisions of large arteries, III, 752; proportion of killed in battle caused by, III, 761; from shot wounds of head, III, 763; I, 127, 256; of face, III, 763; I, 390, 393, 396, 397; of neck, III, 763; of trunk, III, 763; I, 472, 519–528, 611–613, 638, 642; II, 89, 18, 57, 150, 154, 159, 176–179, 190, 320; upper extremities, III, 763; II, 472, 928, 932; lower extremities, III, 763; in shot flesh wounds, III, 37; in shot fractures, III, 416, 448; transportation as cause of, III, 810; treatment of, III, 810; *venous*, see **Veins.**

Hæmorrhoidal Artery, hæmorrhage from, III, 764; II, 316, 326.

Hæmorrhoids, operations for, II, 322; SMITH'S clamp in, II, 322.

Hæmothorax, I, 624–626; II, 155, 173.

Hall's mode of administering chloroform, III, 889.

Hand, shot fractures and contusions of bones of, III, 690, 870; fractures of bones of hand treated by expectation, II, 1020; III, 870; by *excision*, II, 1019; III, 870; by excision and subsequent amputation, III, 870, 871; by *amputation*, II, 1021; III, 871; amputations for miscellaneous injuries of, III, 659, 663, 664.

Harelip, operation for, III, 684.

Head, wounds and injuries of, I, 1–320; *incised* and *punctured* wounds of, I, 1–34; sabre wounds of, I, 1–28; other incised wounds of, I, 28–30; bayonet wounds of, I, 31–34; *miscellaneous injuries* of: railroad accidents, falls, blows, falling trees, kicks, I, 35–69; *gunshot wounds* of, I, 70–320; III, 688; complications in wounds of: gangrene, III, 824; traumatic erysipelas, III, 852; pyæmia, III, 859; tetanus, III, 819. See **Cranium, Scalp.**

Heart, *shot wounds* of, I, 530, 613, 623; II, 51; *incised* wounds of, 571, 534; *bayonet* wounds of, I, 468; action of, visible through wound, I, 535, 597; autopsies in shot wounds of, I, 530, 531, 532; cardiac diseases from wounds of, I, 533; congenital malposition of, III, 437.

Hemiplegia, I, 316; II, 32.

Hepatic Duct, wound of branch of, II, 139; III, 764.

Hepatitis, seldom induced by shot wounds of liver, II, 139; case of, II, 148.

Hermetical Sealing in shot wounds of chest; HOWARD'S method of, I, 497–514; II, 32; autopsies in cases of, I, 503, 504, 505.

Hernia, *abdominal,* following bayonet and sabre wounds, II, 3, 4; following lacerated wounds, II, 5; following incised wounds, II, 129; III, 654; following shot wounds, II, 46, 47, 184, 185; operations for radical cure of, II, 186; *diaphragmatic,* I, 515, 516; II, 185; *inguinal,* I, 596; II, 474, 852; III, 650, 653; *double inguinal,* II, 227; of *lung,* I, 514, 515, 517, 518, 617; II, 147; *phrenic,* II, 25; scrotal, II, 288, 347, 368, 419; *ligation* of hernia, I. 516. See **Cerebral Hernia.**

Herniotomy, II, 186, 187, 271.

Hip Joint, periarticular wounds of, III, 24, 690; shot fractures of, III, 65, 690, 870; treated by conservation, III, 66; *excisions* of, III, 89, 870; primary excisions, III, 92; intermediary excisions, III, 101; secondary excisions, III, 113; *amputations* at, III, 127, 871; primary amputations, III, 131; intermediary amputations, III, 139; secondary amputations, III, 145; amputations at, for disease, III, 665.

Holston's Chisel for removal of depressed bone, I, 320.

Homicide, cases of, during war, III, 641.

Hospital, special, for the treatment of injuries and diseases of the nerves, III, 729.

Hospital Cars, improvised from railway freight cars, III, 958; from railway passenger cars, III, 960; HARRIS car, III, 960; MCCRICKETT'S car, III, 961; car of the Army of the Cumberland, III, 965; U. S. Army hospital car, III, 967.

Hospital Commissary, duties of, III, 912.

Hospital Gangrene, diagnosis of, III, 845; conditions favorable to accession of, III, 849; microscopical appearance of, III. 830–833, 843; at Nashville, III, 832; at Annapolis, III, 830, 836; at West Philadelphia, III, 826; at Frederick, III, 826; at Douglas Hospital, Washington, III, 837; at Memphis, III, 843; in shot flesh wounds of lower extremities, III, 33, 35; in shot fractures of knee joint, III, 416; treatment of, by bromine, III, 834–837, 842–848.

Hospital Knapsack, description and contents of, III, 915.

Hospital Steamers, or floating hospitals, in Western waters, III, 972–981; *City of Memphis,* III, 974; *Louisiana,* III, 975; *R. C. Wood,* II, 975; *D. A. January,* III, 977; *Empress,* III, 981; in Eastern waters, III, 981; *Daniel Webster,* III, 981; *Connecticut,* III, 981; *State of Maine,* III, 982; *J. K. Barnes,* III, 982.

Hospital Tents, III, 920; mode of heating of, III, 921.

Hospital Trains, of the Army of the Potomac, III, 961; of the Army of the Cumberland, III, 962; commissary car, III, 968; baggage car, III, 968; kitchen car, III, 968, 969, 970; surgeon's car, III, 969.

Howard's wire sutures in fractures of femur, III, 350; in excisions of shaft of humerus, II, 820; method of hermetical sealing, I, 497; bone drill, II, 821; ambulance wagon, III, 953.

Humerus, shot contusions of, II, 667, 817; III, 716; partial shot fractures of, II, 668; simple shot fractures of, II, 815; complete shot fractures of, II, 669, 826; III. 690; treatment of, II, 811; by splints of: WELCH, II, 811; HAMILTON, II, 811; PHYSICK, II, 812; ROSE, II, 812; KIRKBRIDE, II, 812; VEDDER, II, 812; SWINBURNE, II, 812; by CLARK'S method of extension, II, 813; by LAWSON'S method of extension, II, 825; excisions in shaft of, II, 675, 819–822, 826; primary excisions, II, 675; intermediary excisions, II, 686; metallic sutures in cases of excision of, II, 820; excision of, for miscellaneous injuries and diseases, III, 658; secondary excisions, II, 690; for amputations in shaft of humerus. See **Arm.**

Hydrarthrus of knee joint, amputation in thigh for, **II, 667.**

Hydrocele, II, 420, 421.

Hydrothorax, I, 472, 624; III, 430.

Hygienic Influences, effect of, on the treatment of wounds, III, 867, 868.

Hyoid Bone, fracture of, in hanging, I, 400.

Hyperostosis in shot contusions of cranial bones, I, 127.

Hypospadia, II, 387; III, 73.

Ileum, rupture of, II, 22, 205; shot wounds of, II, 70, 71, 72, 169, 190; protrusion of, II, 62; enterorrhaphia in shot wounds of, II, 72.

Iliac Artery, *common,* aneurism of, III, 39; wounds of, II, 333, 335, 336; shot perforation of, II, 754; hæmorrhage from, III, 764; ligation of, III, 765, 786; II, 333, 335, 336; III, 39; *external,* aneurism of, III, 239; hæmorrhage from, II, 10; III, 764; ligations, summary of, III, 765, 787; cases, II, 10, 333, 336; III, 39, 77, 84; *internal,* bayonet wound of, II, 335; shot wounds of, II, 330, 331; ligations of, III, 765, 786.

Iliac Region, penetrations of, mistaken for wounds of abdomen, II, 213, 214.

Iliac Vein, *internal,* injuries of, II, 190; III, 111, 816; *external,* emboli in, III, 191.

Ilio-Lumbar Artery, hæmorrhage from, II, 218, 327; III, 764.

Ilium, shot fractures of, II, 212–237; liability to pyæmia in, II, 212; danger of purulent infiltration in, II, 212; shot fractures of both iliac bones, II, 215, 216; excisions of portions of, II, 230–233.

Impalement, II, 204.

Incised Wounds (not sabre), III, 640, 652; of head, I, 28–30, 308; of neck, I, 400; of spine, I, 424; of chest, I, 470; of abdomen, II, 4, 31, 61, 76, 129; of pelvic cavity, 263, 343; of lower extremities, III, 7, 361.

Inflammation controlled by ligation of femoral artery, III, 377, 383.

Inhaler, CHISOLM'S, for the administration of chloroform, III, 889.

Innominate Artery, wound of, I, 521, 606; aneurism of, I, 521; II, 808; hæmorrhage from, I, 520; III, 763.

Insanity, in fractures of cranium, I, 237, 238; in amputation of thigh, III, 229; in amputations of leg, III, 295, 486, 518.

Instruments, contents of pocket case of, III, 919; of field case of, III, 919; of operating case of, III, 919; for resection, II, 256, and plate opposite; HEINE'S osteotome, MOLLET'S saw, gnawing bone forceps, LEGOUEST'S curved gouge and chisel, U. S. A. gouge and chisel, NÉLATON'S bone forceps, II, 256.

Intercostal Artery, aneurism of, II, 597; wounds of, I, 525, 526, 606; ligations of, III, 765, 774; I, 550, 551, 552.

Interosseous Artery, of *forearm:* aneurism of, III, 808; wounds of, II, 456, 469, 911; accidentally wounded during operation, II, 954; hæmorrhages from, III, 764; ligations of, II, 454, 961, 988, 1004; III, 765, 785; of *leg,* hæmorrhage from, III, 528, 764; ligation of, III, 518, 765, 803.

Intestines, shot wounds of, III, 689; *large,* punctured and incised wounds of, II, 76; shot wounds of, II, 76; *small,* punctured and incised wounds of, II, 61; shot wounds of, II, 64; of duodenum, II, 67; of jejunum, II, 68; of ileum, II, 70; rupture of intestines, II, 3, 22, 26; operations on large intestines, II, 109; anaplasty, II, 111; enterorrhaphia, II, 112; protrusion of, II, 32, 34, 62, 72, 73, 75, 183, 260; protruding intestines returned, II, 62, 73, 260; worms in wounds of, II, 95.

Involucra of bones of the leg, III, 478, 492, 539, 545; of the femur, III, 189, 196, 198, 226, 241, 256, 293, 310, 317, 319.

Iridectomy, III, 681, 682, 683.

Ischium, contusion of, II, 254; shot fractures of, II, 241–245, 255; excisions of portions of, II, 245.

Jaundice, in shot wounds of abdomen and pelvic cavity, II, 138, 145, 160, 291, 304.

Jejunum, rupture of, II, 22, 23; bayonet wound of, II, 42; punctured wounds of, II, 61; protruding after bayonet puncture, II, 61, 62; shot wounds of, II, 68, 69, 72.

Jugular Vein, *external,* injuries of, I, 407, 411, 412, 491; III, 816; *internal,* injuries of, I, 383, 392, 397, 420; III, 750, 816; accidentally cut during operation, I, 392, 397; ligation of, I, 383, 392, 397.

Kidney, shot wounds of, II, 163–172, 202; III, 689; autopsies, II, 168, 169, 170; rupture of, II, 20, 21, 26.

Knapsack, Hospital, description and contents of, III, 915.

Knee Joint, periarticular wounds of, III, 24–32, 690; bayonet wounds of, III, 360, 686; punctured and incised wounds of, III, 6, 359; arrow wound of, III, 653; miscellaneous injuries of, III. 360; incised wounds of, followed by amputation of, III. 362; shot contusions, III, 364, 690,

Knee Joint—[Continued.
716, 870; shot contusions of, followed by amputation, III, 363; shot fractures of, III, 367, 870; shot fractures of, treated by *conservation*, III. 368, 384, 411, 417, 418, 419, 870; by *excision*, III, 384, 419–422; primary excisions, III, 386; intermediary excisions, III, 391; secondary excisions, III, 394; by *amputation*, III, 397–407; primary amputations, III, 398; intermediary amputations, III, 404; secondary amputations, III, 407; amputations following excisions, III, 870; re-amputations in amputations at knee joint, III, 871; modes of amputation: HOIN'S, LÉVEILLÉ'S, N. SMITH'S, VELPEAU'S, BAUDENS', ROSSI'S, PANCOAST'S, SYME'S, CARDEN'S, MELCHIORI'S, STOKES' modification of GRITTI'S, III, 424-426; shock in wounds of, III, 412; perforation of, without lesion of bones, III, 415, 416; missile lodged in knee joint, III, 372, 416; antiseptic treatment of fractures of, on field of battle, III, 418, 419; GRITTI'S osteoplastic operation, III, 283, 424.

Lachrymal Canal, destruction of, I, 345. 368, 370.

Lachrymal Fistula, I, 329, 358.

Lachrymal Sac, operation on, for chronic inflammation, III, 683.

Lance Wounds, I, 34; II, 34.

Langer's Ambulance Wagon, III, 955, 956.

Laryngotomy, I, 415, 418; III, 684.

Larynx, incised wound of, I, 400; shot wounds of, I, 406; III, 688; death caused by clot of blood in, I, 354; opened in suspended animation following administration of chloroform, II, 841.

Leg, punctured flesh wounds of, III, 6, 7; *shot flesh wounds* of, III, 8; *shot contusions* of bones of, III, 427, 690, 716, 870; shot contusions followed by amputation, III, 430; *shot fractures* of bones of, III, 432, 690, 870; treated by conservation, III, 432, 564; treated by PETIT'S fracture box, III, 568; by splints, III, 568; treated by excision, III, 444, 570, 870; primary excisions, III, 445; intermediary excisions, III, 453; secondary excisions, III, 456; excisions in the bones of the leg followed by amputation, III, 870; amputations in, III, 460, 572, 871; primary amputations, III, 491; intermediary amputations, III, 512; secondary amputations, III, 537; re-amputations after amputations in leg, III, 870, 871; protrusions of bone after amputations, III, 576; amputations for *miscellaneous injuries* of, III, 670; excisions for miscellaneous injuries of, III, 657, 658, 659. See **Fibula, Tibia.**

Ligations of *arteries* in shot wounds, III, 765, 813; percentage of fatality in, III, 813; ligations in continuity, III, 814; above and below wound, III, 814; in wound, III, 814; ligations in stump, III, 814; rarely required on field of battle, III, 815; of *veins* in *shot wounds*, III, 816; ligations for *miscellaneous injuries*, III, 679; ligations in wounds of the *head*, I, 160, 225, 241, 244, 255, 269, 288, 298, 313, 315; of the *face*, I, 332, 339, 346, 347, 349, 350, 367, 396, 397; of the *neck*, I, 419; of the *spine*, I, 455; of the *chest*, I, 537–556; of the *abdomen*, II, 191; of the *pelvis*, II, 326, 327, 330, 333, 337; of the *upper extremities*, II, 436, 442–454; of the *lower extremities*, III, 7, 38–52, 172, 353. See **Aorta,** etc.

Lightning Stroke, III, 655.

Lingual Artery, hæmorrhages from, III, 763; wounds of, I, 351, 421; III, 763; ligations of, I, 397, 421; III, 765, 771.

Lithotomy, II, 269–299.

Lithotrite, CIVIALE'S, II, 378.

Litters, III, 923; SATTERLEE'S, III, 923; HALSTEAD'S, III, 924; SANITARY COMMISSION'S, III, 925; CONFEDERATE STATES', III, 925; SCHELL'S, III, 925; litter carriage, III, 926; mule litter: BRITISH, III, 928; FRENCH, III, 931; two-horse, III, 926; litters suspended in hospital cars, III, 958.

Liver, *ruptures* of, II, 16; *bayonet* wound of, I, 469; *punctured* and *incised* wounds of, II, 129; *shot* wounds of, II, 131; III, 689; metastatic abscesses of, II, 133; escape of bile from, II, 142, 143.

Lumbar Ecchymosis as a sign of penetrating wound of chest, I, 575.

Lumbar Nerve, shot wound of, II, 330.

Lumbar Vertebræ, miscellaneous injuries of, I, 426; shot injuries of, I, 441–449, 451, 458–462, 584; II, 36, 48, 72, 155, 168, 170.

Lumbrici, escape of, in wounds of abdomen, II, 42, 64, 68, 71, 94, 195.

Lung, *sabre* perforation of, I, 466, 467; *bayonet* wound of, I, 467, 468, 469, 470; *knife* wounds of, I, 470, 471; *shot* wounds of, I, 491; shot wounds of both, I, 495, 634; autopsies in wounds of, I, 492, 494, 497; collapse of, I, 631, 632; balls lodged in, I, 489, 505, 552, 585; ball removed from, I, 32, 585; foreign bodies lodged in, I, 493; fragments of clothing expectorated after wound of, I, 584.

Maggots, in wounds, III, 867; precaution against, III, 867; cases of, I, 241, 348; II, 754; III, 20, 454, 530; in stump, III, 269.

Malar Bone, shot fractures of, I, 345, 381; excisions of, I, 383; miscellaneous injuries of, I, 324.

Malleolar Artery, *external*, wounds and hæmorrhages of, III, 764.

Malleolus, *external*, excisions of, III, 589, 593; *internal*, excisions of, III, 586, 591.

Mammary Artery, *external*, shot wounds of, I, 519, 523, 524; on ligation of, I, 524; *internal*, shot wounds of, I, 523, 524, 548; III, 764; on ligations of, I, 548; II, 177; III, 765, 774.

Materia Chirurgica, III, 914; hospital knapsacks, III, 914; field companion, III, 915; medicine pannier, III, 916; medicine wagons of: E. HAYES & CO., III, 916; of J. DUNTON, III, 916; of PEROT, III, 917; of AUTENRIETH, III, 918. Surgical instruments: capital operating case, III, 919; minor operating case, III, 919; pocket case, III, 919; field case, III, 919. Tents: hospital, III 920; SIBLEY, III, 920.

Maxilla, *upper*, miscellaneous injuries of, I, 324; shot fractures of, I, 381; excision of, I, 348, 354, 383, 398; *lower*, miscellaneous injuries of, I, 324; shot fractures of, I, 381; excisions of, I, 347, 351, 362, 383; splints and apparatus in treatment of shot fractures of lower, I, 391.

Maxillary Artery, shot wounds of *internal*, I, 346, 351, 352, 360; hæmorrhages from, III. 763.

Median Nerve, bayonet wound of, II, 827; III, 687; shot wounds of, I, 479; II, 447, 946, 1020; excisions of, II, 461, 464, 470, 778.

Mediastinum, shot wounds of, I, 486, 535, 589.

Medical Department, expenditures of, during the war, III, 902.

Medical Descriptive List, form of, I, XVII.

Medical Director of corps, duties of, III, 903–906.

Medical Inspector of corps, duties of, III, 906.

Medical Staff, III, 899; casualties among, I, XXX–XXXII; III, 901.

Medicine Panniers, III, 916.

Medicine Wagons, III, 917; PEROT'S, III, 917; DUNTON'S, III, 917; AUTENRIETH, III, 918.

Medio-tarsal amputations, III, 628.

Medullary Artery, hæmorrhage from, III, 224.

Medullary Canal, of femur, ball lodged in, III, 176; gangrene of, III, 225.

Meloplasty, I, 369.

Meningeal Artery, ruptures of, II, 49, 54, 60, 125; wounds of, I, 229; hæmorrhage from, III, 763.

Meningitis, Spinal, cases of, I, 439, 444.

Mercurial Poisoning, I, 375.

Mesenteric Artery, punctured wound of, II, 62; aneurism of, II, 25; shot wound of, II, 155; hæmorrhage from, III, 764; ligations of branches of, II, 62.

Mesentery, ruptures of, II, 23, 24; shot wounds of, II, 174, 175; III, 689; ball lodged in, II, 179.

Metacarpal Bones, shot fractures of, II, 1019.

Metallic Sutures, in excisions of shaft of humerus, II, 820.

Metastatic Abscesses, in lung, I, 628, and plate opposite; in liver, II, 133.

Metatarsal Bones, bayonet wound of, III, 617, 686; shot fractures of III, 618; excisions of, III, 622.

Miscellaneous Injuries, III, 640; operations for, III, 657.

Missiles, nature and seat of injury of, in shot wounds, during the war, III, 696; *small arm missiles*, round ball, III, 697; more prone to lodge than conoidal, III. 757; buck and ball, III, 697; rifle balls, III, 697; slugs, III. 700; from fowling pieces, III, 700; SHALER'S sectional bullet, III, 700; erratic course of small missiles, III, 710; effects of small missiles, III, 709, 710; distortions of small missiles, III, 710; *large missiles*, III, 697; shrapnel shots, III, 697; spherical case shot, III, 698; bolts, III, 698; rifled shot: WHITWORTH, PARROT, III, 698; shells, III, 699; railroad iron as missiles, III, 697; effects of missiles on blood-vessels, III, 750; on bony structure, III, 713; lodgement of, III, 757; early extraction of, III, 867; encystment of, III, 867.

Moral Influences, effects of, on the treatment of wounds, III, 867, 868.

Mouth and Appendages, operations on, for miscellaneous injuries and diseases, III, 684.

Mule Litters, III, 928.

Multiple Wounds, case of, I, 334, 340; II, 217, 241, 408; III, 372, 409, 868.

Muscular Tissue, effects of gunshot projectiles on, III, 712; repair of shot wounds of, III, 714; pyæmia in shot lesions of, III, 713.

Musculo-spiral Nerve, shot wounds of, II, 464 (note), 673 (note), 861; rupture of, III, 644.

Nasal Bones, shot fractures of, I, 381; miscellaneous injuries of, I, 324.

Neck, sabre and bayonet wounds of, I, 399, 400; III, 686; miscellaneous injuries of, I, 400; III, 653; shot injuries of, I, 401–424; III, 688; wounds of, by conoidal balls, I, 402; lodgement of missiles in, I, 403; extraction of missiles from, I, 405; torticollis in shot wounds of, I, 405; wounds of the larynx and trachea, I, 406; aphonia in, I, 407; wounds of the pharynx and œsophagus, I, 408; paralysis in, I, 408; complications in shot wounds of: hæmorrhage, I, 411; traumatic erysipelas, I, 412; III, 852; sloughing and gangrene, I, 413; III, 824; pyæmia, I, 413; III, 859; tetanus, III, 819; operations on the, I, 415.

Nerves, shot wounds of, III, 725; effects of missiles and projectiles on, III, 725, 726, 730, 742; paralysis following shot wounds of, III, 726; wounds of nerves of special sense, III, 738; concussion or commotion of, III, 741; contusion of, III, 741; cicatricial pressure on, III, 741; tetanus following wounds of, III, 743; immediate deaths from injuries of, III, 743; altered nutrition following injuries of, III, 743, 744; excessive skin secretion following injuries of, III, 746; neuralgia following injuries of, III, 746; motor paralysis, III, 748; wounds of nerves of the neck, I, 423; of the chest, I, 634; of the pelvis, II, 339, 342, 423; in flesh wounds of the upper extremities, III, 461–468; of the lower extremities, III, 9; ball pressing on, I, 410; involved in cicatrix, II, 736; *excisions or removals of portions of nerve,* II, 461, 462, 618, 736, 747, 970, 973; III, 11, 492, 495, 820; *electricity* in injuries of, I, 387, 409; II, 461, 1020; III, 9; nerve included in ligation of subclavian, I, 540; special hospital for treatment of injuries and diseases of, III, 729; wounds of: *axillary* plexus, I, 410; II, 461, 492; *brachial* plexus, I, 409, 410, 478, 522, 560; *cervical* plexus, I, 405; *crural* nerve, I, 446; II, 339, 400; III, 10, 74, 823; *cutaneous* nerve, II, 462, 463, 464, 470, 928; III, 9, 11; excision of cutaneous nerve, II, 462, 470; *dental* nerve, I, 358, 362, 397, 398; *facial* nerve, I, 117, 362, 387; *lumbar* nerve, II, 330; *median* nerve, I, 479; II, 447, 461, 464, 469, 470, 778, 827, 946, 1020; III, 687; excision of median, II, 461; *musculo-spiral* nerve, II, 461, 464, 673, 861; III, 644; *optic* nerve, I, 326, 327, 335, 344; *peroneal* nerve, III, 492, 495; *plantar* nerve, III, 617; *pneumogastric* nerve, I, 357; *popliteal* nerve, III, 9, 11, 55, 56, 95, 103, 173; *radial* nerve, II, 452, 467, 925, 938; *sacral* nerve, I, 449; II, 261; *sacral* plexus, II, 232, 253, 254; *saphenous, long,* nerve, III, 9, 10, 11; *sciatic* nerve, II, 323, 327, 339, 340, 346, 354, 366, 406; III, 9, 10, 22, 56, 196, 311, 687. *Spinal nerves,* I, 577, 584; II, 163, 340; necrosis involving *sympathetic* nerve, II, 466; *thoracic* nerve, I, 536; *tibial,* II, 412; anterior tibial, III, 7, 9, 11, 55; posterior tibial, III, 9, 11, 12, 20, 54, 56; excision of posterior tibial, III, 58; *ulnar,* II, 461, 465, 466, 469, 843, 861.

Neuralgia, *traumatic,* I, 478; probably caused by lodgement of ball, II, 232; relieved by removal of ball, II, 236; treatment of, II, 342.

Nervous Anxiety, in shot wounds of chest, I, 638.

Neuroma, II, 463, 465, 466, 623, 628, 699; III, 624.

Neurotomy, II, 465, 623, 628, 699.

Nose, wounds of, I, 386; protracted discharge from wounds of, I, 387.

Occipital Artery, wounds of, I, 80, 82, 83, 124, 132, 456; hæmorrhages from, III, 763; ligations of, I, 456; III, 765, 771.

Œdema of Glottis, I, 404, 417, 418.

Œsophagus, incised wound of, I, 400; shot wounds of, I, 536, 606, 634; III, 618.

Omentum, ruptures of, II, 23; shot wounds of, II, 36, 174; III, 689; ball held in folds of, II, 174; protrusion of, I, 449; II, 32, 33, 34, 169, 175, 180, 182, 183; removal of protruding, II, 32, 77, 91, 181, 182; sloughing of, I, 516.

Ophthalmitis, general, incisions in, I, 345.

Opium, use of, in injuries of abdomen, II, 17, 27, 207.

Optic Nerve, shot wound of, I, 326, 327, 332, 335, 344.

Orthopnœa, in chest wounds, I, 480, 505, 529; in wounds of the abdomen, II, 135, 155.

Os Calcis, shot contusion of, III, 617; shot fractures of, III, 618, 619; excisions of, III, 624, 625, 626, 627.

Osteoplasty, in wounds of the testes, II, 410, 416.

Osteomyelitis, following injuries of the upper extremities, II, 648, 715, 754, 788; of the lower extremities, III, 146, 148, 149, 152, 153, 156, 157, 193, 223, 280, 281, 290, 297, 301, 312, 315, 442, 530; resulting from shot contusions of femur; simple, III, 716; gangrenous, III, 171, 717.

Osteophytes, in shot contusions of cranial bones, I, 127; in injuries of the femur, III, 31, 202, 225, 291.

Osteo-sarcoma, amputation of thigh for, III, 666.

Palate Bone, shot fractures of, I, 381.

Palatine Artery, hæmorrhage from, I, 346.

Palmar Arch Arteries, incised wound of, II, 437; hæmorrhage from II, 437, 448, 449, 459; III, 764; ligations of, II, 454; III, 765, 785.

Pancreas, shot wounds of, II, 158, 159, 130, 161, 202; III, 689; ball lodged in, II, 159, 160; protrusion of, II, 158; excision of, II, 158.

Paracentesis, thoracis: for hydrothorax, I, 573; for metastatic abscesses and empyema, I, 573; for idiopathic pleurisy, I, 573; for effusions following perforations of the chest, I, 574; abdominis, for ascites, II, 191, 192; naturalis, I, 576.

Paralysis, after shot fractures of cranium, I, 226, 227, 228, 229, 230, 278, 287; after wounds of neck, I, 409, 410; after wounds of chest, I, 478, 479; after wounds of abdomen, II, 14; of bladder and rectum, II, 222, 229, 247, 248; relieved by removal of ball, I, 424; electricity in, I, 442.

Parotid Gland, wounds of, I, 406, 411; ball embedded in, I, 305.

Patella, shot fractures of, III, 367; shot perforations of, III, 371, 373, 380; percentage of fatality of shot injuries of, III, 416; shot contusions of, III, 364; bayonet wound of, III, 360; miscellaneous injuries of, III, 651.

Pelvis, sabre and bayonet wounds of, III, 686; punctured and incised wounds of, II, 323, 326, 335, 336, 423; shot contusions of, III, 716; shot fractures of, II, 211–254, 424–426; III, 689; excisions of pelvic bones, II, 255. See **Ilium, Pubis, Ischium, Sacrum, Coccyx,** shot injuries of parts contained in pelvis, II, 257–406.

Penis, incised wounds of, II, 343, 344; bayonet wounds of, II, 344; shot wounds of, II, 345–349; laceration of, II, 374; ball encysted in, II, 345; ball lodged in, II, 345, 346; ball extracted from, II, 345, 346; use of catheter in wounds of, II, 348; amputation of, II, 347, 349.

Perforating Arteries, hæmorrhages from, III, 50, 239, 267, 764; ligations of, III, 50, 239, 267, 765, 799.

Periarticular Wounds, of the shoulder joint, II, 502; of the elbow joint, II, 829; rarity of, in wounds of the wrist, II, 995; of the hip joint, III, 25; of the knee joint, III, 28; of the ankle joint, III, 31; summaries of, III, 690.

Pericarditis, in wounds of the chest, I, 529, 530, 578, 587, 622.

Pericardium, wounds of, I, 528, 529, 606; ball lodged in, I, 528; autopsies in wounds of, I, 528, 529.

Perinæum, shot wounds of, II, 243, 244, 399; ball extracted from, II, 399; lacerated wound of, II, 402.

Perineal Fistula, after shot wounds, II, 365.

Perineal Section (perineotomy), ball removed by, II, 260; fragment of bone removed by, II, 399, 400; portions of bayonet scabbard and of bayonet removed by, II, 245.

Periostitis, in shot contusions of cranial bones, I, 102, 127; of scapula, I, 564; in wounds of hip joint, III, 79; in fractures of bones of lower extremities, III, 183, 310, 313, 314, 428, 455, 515, 518.

Peritonitis, *traumatic,* in wounds of spine, I, 427, 444, 446, 449; in wounds of chest, I, 586; in wounds of abdomen, II, 5, 7, 12; general observations on, II, 199, 200, 207, 208.

Peroneal Artery, *traumatic,* aneurism of, III, 808; wounds of, III, 456; hæmorrhage from, III, 515, 764; ligations of, III, 51, 450, 456, 526, 765, 805.

Peroneal Nerve, excisions of, III, 492, 495.

Phalangeal Bones, of *hand,* shot fractures of, II, 1019; of *foot,* shot fractures of, III, 618; excisions of, III, 626.

Pharyngitis, in wounds of the neck, I, 350, 416.

Pharynx, shot wounds of, I, 414; III, 688.

Phlebotomy, in shot wounds of chest, I, 649.

Phrenic Artery, hæmorrhage from, II, 177; III, 764.

Phimosis, operations for, II, 343, 361, 374; non-traumatic, II, 386.

Plantar Artery, hæmorrhage from, III, 764; ligations of, III, 552, 673, 678, 765, 804, 805.

Plantar Nerve, shot injury of, III, 617.

Plastic operations, in injuries of the face, I, 368–380; for fæcal fistula, II, 79.

Pleural Cavity, incisions into, after empyema, I, 581; apparatus for effusions in, I, 627.

Pleurisy, *traumatic*, in penetrating wounds of chest, I, 617, 618; cases of, 470, 492, 574, 576.

Pneumogastric Nerve involved in wound, I, 357.

Pneumonia, *traumatic*, in penetrating wounds of chest, I, 619–622; II, 483, 486, 499, 500; in shot wounds of the back, II, 432.

Pneumothorax, in shot wounds of chest, I, 633; cases of, I, 493, 494, 520.

Poisoned Wounds, III, 640, 656, 663.

Popliteal Artery, wounds of, III, 14, 17, 18, 47, 51, 56, 173, 226; hæmorrhages from, III, 764; aneurisms of, III, 14, 54, 55, 58, 542, 680, 808; occlusion of, III, 14, 18, 388; ligations of, III, 14, 50, 51, 54, 175, 383, 404, 569, 765, 800.

Popliteal Nerve, shot injuries of, III, 9, 11, 55, 56, 173.

Popliteal Vein, injuries of, III, 55; hæmorrhage from, III, 816; ligations of, III, 383.

Priapism, persistent, I, 209; II, 303 (note); III, 81.

Profunda Artery, of *arm:* injuries of, II, 448, 585, 649, 736; hæmorrhages from, III, 764; aneurism of, III, 808; ligation of, II, 454, 681, 736; III, 765, 782; of *thigh:* injuries of, III, 47, 49, 55, 172; hæmorrhages from III, 764; aneurisms of, III, 49, 808; ligations of, III, 44–49, 172, 233, 236, 765, 798, 799; re-ligations of, III, 44–47, 48.

Projectiles used during the war, III, 695–704; effects of large, III, 704. See **Missiles, Balls.**

Prostate, shot wounds of, II, 303, 304, 313, 423; III, 689; autopsy in shot wounds of, II, 304; ball lodged in, II, 304.

Prostration after anæsthesia, III, 897.

Prothetic Apparatus, in excisions at the shoulder joint, II, 568, 573, 580, 594; in excisions in shaft of humerus, II, 675; in excisions at elbow joint, II, 849, 907, 908; in amputations in forearm, II, 968; in fractures or excisions at wrist or ankle joint, II, 1015; for amputations at hip joint, III, 131, 162; in amputations in the thigh, III, 224.

Pseudarthrosis, after fractured jaw, I, 361; in shot fractures of the humerus, II, 673, 676, 680, 682, 687; frequency of, after excisions in shaft of humerus, II, 696; after excisions of elbow, II, 853, 854, 856, 858, 877, 890; after excisions in forearm, II, 934, 940, 945, 963, 964; in periarticular wounds of hip joint, III, 25 (note); in fractures of femur III, 186, 198, 199; after excisions in shaft of femur, III, 202; after excisions in bones of leg, III, 447, 450, 456, 457, 459, 460 556, 572.

Pterygium, operation for, III, 681, 682, 683.

Ptosis, in shot wounds of cranium, I, 115, 186, 358.

Pubic Bones, shot fractures of, II, 237–240; table of cases of, II, 255; autopsies after shot fractures of pubic bones, II, 238, 239, 240.

Pudic Artery, traumatic aneurism of, III, 808; wound of, II, 357; hæmorrhages from, III, 764; *external*, II, 326; III, 764; ligation of, II, 186, 326; III, 765, 798; *internal*, aneurism of, II, 252; hæmorrhage from, II, 324, 327; wound of, II, 304; bayonet wound of branch of, II, 323.

Pulmonary Artery, thrombi in, II, 967; hæmorrhage from, III, 764.

Punctured Wounds, number of, during the war, III, 640; of scalp, I, 30; of cranium, I, 31; of face, I, 321, 323, 324; of neck, I, 399; of chest, I, 466, 467, 509; of abdominal parietes, II, 3; of abdominal cavity without visceral injury, II, 31, 202; of jejunum, II, 42; of stomach, II, 42, 43, 44, 57; of small intestines, II, 61; of mesenteric artery, II, 62; of large intestines, II, 76; of diaphragm, II, 76; of colon, II, 76; of liver, II, 129; of spleen, II, 149; of kidney, II, 162; of bladder, II, 263; of urethra, III, 652; of blood-vessels of pelvis, II, 323; of pudic artery, II, 323; of iliac artery, II, 335; of penis, II, 344; of back, II, 429; of upper extremities, II, 435; of brachial artery, II, 436; of clavicle or scapula, II, 473, 474; of elbow joint, II, 827; of metatarsal bones, III, 617; of lower extremities, III, 5; of femoral artery, III, 6; of knee joint, III, 359, 653; of leg, III, 6.

Pus, extravasation of, in shot wounds of abdomen, II, 197; cases of, II, 24, 67, 104, 135, 136.

Pyæmia, tabular statement of cases of, III, 858; percentage of fatality in cases of, III, 858; complicated with other diseases, III, 858; time of appearance of, after injury, III, 859, 860; duration of, III, 860; after shot flesh wounds, III, 860; after shot fractures, III, 860; treatment of, III, 860, 861; in shot lesions of muscular tissue, III, 713; post mortem appearances in cases of, III, 862–866; after shot fractures of cranium, I, 256; of the face, III, 859; after shot wounds of the neck, I, 412, 413; III, 859; after shot wounds of the spine, I, 454; of chest, I, 472; after shot fractures of pelvis, II, 212, 231, 239, 247; in fractures of upper extremities, III, 859; in fractures of forearm, II, 932; in fractures of lower extremities, III, 858, 859; in flesh wounds of lower extremities, III, 32, 33; in fractures of femur, III, 352; in fractures of knee joint, III, 416; in fractures of leg, III, 569.

Pyohæmia, III, 857.

Radial Artery, incised wound of, II, 436; shot wounds of, II, 452, 455, 469, 840, 914; hæmorrhages from, II, 452, 453; III, 764; aneurisms of, II, 969, 1010; III, 808; ligations of, II, 436, 452, 453, 469; III, 765, 782; summary of ligations of, III, 783; shot wound of radial and ulnar, III, 764.

Radial Nerve, shot injuries of, II, 452, 467, 925, 938.

Radius, shot fractures of, II, 922; treated by expectation, II, 927–932; followed by excision, II, 936.

Radius and Ulna, shot fractures of, II, 923.

Railway Transportation of wounded, III, 957–971.

Ramrod, abdominal cavity transfixed by, without injury to viscera, II, 33; missile extracted by, II, 251.

Re-amputations, III, 870, 871.

Recto-vesical Fistula, after shot wounds, II, 309, 310, 313.

Rectum, shot wounds of, II, 305; III, 689; lesions of, without injury to other organs of pelvis, II, 423; autopsies in shot wounds of, II, 316, 317, 318; foreign bodies removed from, II, 322.

Rectus Muscles, rupture of, in lacerated wound of abdomen, II, 5.

Reflex Paralysis in shot wounds, III, 726, 729–738.

Remote Results of wounds and injuries, sources from whence obtained, I, xix.

Report of surgical operations, form of, I, xvi; of wounded, form of, I, xvi.

Resections, instruments for, see plate opposite II, 256. See **Excisions.**

Rhinoplasty, I, 372.

Ribs, shot fractures of, I, 488, 566; III, 689; shot fractures of, without lesion of thoracic cavity, I, 446; fractures of, not shot, I, 599; excisions of, portions of, I, 566, 570, 598.

Rifle-balls, of Springfield musket, III, 697; of Enfield musket, III, 697; of Austrian musket, III, 697; of Burnside rifle, III, 697; of Spencer rifle, III, 697; of Sharp's carbine, III, 697; of Green's rifle, III, 697; of Colt's army pistol, III, 697; superiority of, over round ball, III, 694, 697.

Rucker ambulance wagon, III, 952, 953.

Sabre Wounds, of scalp, I, 1, 308; fracturing cranium, I, 16, 308; of face, I, 321, 382; of neck, I, 399, 400; of chest, I, 466, 471; of abdominal parietes, II, 3, 8; penetrating abdominal cavity, II, 32, 202; of small intestines, II, 61; of large intestines, II, 76; of liver, II, 129; of urethra, II, 374; of back, II, 429; of upper extremities, II, 435, 436; of scapula, II, 473; of elbow joint, II, 828; of forearm, II, 918; of lower extremities, III, 5, 7; summary of sabre wounds, III, 685, 686; mortality of sabre wounds, III, 686.

Sacral Nerves, wounds of, I, 449; II, 261; wounds of plexus of, II, 232, 253, 254, 341.

Sacro-lumbar Nerves, shot injury of, II, 340.

Sacrum, shot fractures of, II, 246–251; excisions of portions of, II, 251; portion of, removed by trephine, II, 251; lodgement of 12-pound shell in, II, 248.

Saliva, profuse escape of, in shot wounds of face, I, 369, 370, 371, 372, 375.

Salivary Fistula, cases of, I, 330, 368, 369; treatment of, I, 380, 387.

Saphenous Nerve, injury of long, III, 9, 10, 11.

Sarcocele, II, 418.

Scalds and Burns, cases of, during the war, III, 641.

Scalping, I, 315.

Scalp, injuries of, I, 1–16, 28–31, 35, 70–95, 308; *sabre wounds* of, I, 1–16; summary of cases of, I, 16, 308; sutures in scalp wounds, I, 1–16, 25; adhesive plaster in, I, 15, 16; *other incised wounds* of, I, 28–30, 308; *bayonet wounds* of, I, 30, 31; *contusions* and *lacerations* of, I, 35, 38, 39–42, 43, 45, 47, 51; FRIAR'S balsam in scalp wounds, I, 64; edges of wound approximated by tying hair, I, 64; interrupted sutures in scalp wounds, I, 64; sabre and bayonet wounds of, III, 686; *shot wounds* of, I, 70–95; III, 688; tabular statement of shot wounds of, I, 70; scalp wounds complicated with intercurrent diseases, I, 85–88; compression of brain in scalp wounds, I, 75, 76; coma, I, 75, 76; ball extracted from scalp, I, 92; foreign bodies lodged in, I, 92; seton wounds of scalp, I, 90, 91, 95.

Scapula, sabre wounds of, II, 473; III, 686; punctured fractures of, II, 474; shot fractures of, II, 474–481; III, 690, 870; remarkable fissuring of, II, 488; exfoliations of, II, 482, 487; autopsies in shot fractures of II, 488, 489, 490; excisions of portions of, I, 562, 566; II, 492–495, 496, 497; III, 657, 658; excision of entire, II, 499 (note); trephining of portion of, II, 492.

Sciatic Artery, shot wound of, II, 326; hæmorrhages from, II, 326, 327; III, 764; aneurism of, III, 808; ligations of, II, 326, 765, 787.

Sciatic Nerve, bayonet wounds of, II, 323; III, 687; shot wounds of, II, 100, 179, 252, 339, 340, 355; III, 9, 10, 22, 56, 60, 139, 196, 311.

Scrotum, shot wounds of, II, 419; ball extracted from, II, 419.

Septicæmia, II, 351; III, 857, 858. See **Pyæmia.**

Sequestra, removal of, II, 715; III, 212, 224, 439, 459, 520, 522.

Seton Wounds, in injuries of the scalp, I, 90, 91, 95; in injuries of the ilium, II, 213, 227.

Shells, injuries by, III, 696; appearance of injuries by, III, 711; lodgement of, III, 705, 706; lodgement of 12-pound shell in sacrum, II, 248. See **Missiles.**

Shock, in shot wounds of chest, I, 639; in shot wounds of the abdominal parietes, II, 13; in penetrating wounds of abdomen, II, 30; as a primary symptom of shot wounds, III, 759; death from shock of wound or operation, II, 490,541, 642, 644, 760, 979, 990; III, 298, 299, 300, 301, 302, 308, 315, 321, 322, 459, 661, 662, 669, 670, 676.

Shot Wounds, number of cases of, treated during the war, III, 685, 688; regional frequency of, III, 691, 692; relative frequency of, III, 691, 692; definition of, III, 694; primary symptoms of: pain, III, 760; shock, III, 759; hæmorrhage, III, 762; entrance and exit wounds, III, 711; early examination of, III, 867; early treatment of, III, 867; primary dressing of, III, 867; maggots in, III, 867; multiple wounds, III, 868, 869; influence of hygienic and moral conditions on treatment of, III, 868; effects of climate on treatment of, III, 867. See shot wounds of: **Head, Face, Neck, Chest, Spine, Abdomen, Pelvis, Back, Upper** and **Lower Extremities;** for shot contusions, see **Contusions;** for shot fractures, see **Fractures.**

Shoulder Joint, shot fractures of, II, 502; III, 690, 870; periarticular wounds of, II, 502; III, 690; shot fractures of, treated by expectation, II, 502–519, 656; III, 870; hæmorrhage in shot fractures of, II, 513, 514; autopsies in shot fractures of, II, 510, 511, 512, 513; shot fractures of, treated by excision, II, 519-613, 664; III, 870; treated by amputation, II, 613, 655; III, 871.

Sibley Tents, used as hospital tents, III, 920.

Simple Dressings in shot wounds of chest, I, 642.

Simple Shot Fractures, III, 704, 705; of the humerus, II, 815; of the radius, II, 929; of the tibia and fibula by cannon ball, III, 440.

Skin Grafting, in shot wounds of back, II, 430, 431.

Small Arms, projectiles from and seat of injury in wounds by, III, 696; effects by missiles from, III, 708, 709. See **Missiles.**

Solid Shot, summary of injuries by, III, 696.

Spermatic Artery, hæmorrhage from, II, 337; III, 764; ligations of, II, 337; III, 684, 765, 788.

Spermatic Cord, shot wounds of, II, 417; III, 689; cases of, II, 339, 413, 415.

Sphincter, division of, for fistula, II, 315, 321; stricture of, after shot wounds, II, 312, 314, 315; paralysis of, II, 310, 312.

Spinal Canal, incised wound of, I, 425; shot wounds of, II, 154, 155; balls lodged in, I, 435, 436, 438, 439, 440, 443, 444, 447, 449, 452, 453, 457; perforation of, I, 444, 447; ball extracted from, I, 444.

Spinal Cord, laceration of, I, 426, 427, 431, 433, 435, 436, 438, 440, 443, 444, 447, 458; perforation of, I, 437, 446, 452; severed, I, 439, 444; II, 339; compressed, I, 426, 438; gangrene of, II, 169; exposed, II, 229.

Spine, miscellaneous injuries of, I, 426–429; III, 643, 649; incised wounds of, I, 425; shot wounds of, I, 430–460; III 689; concussion of, I, 427, 427, 429, 465; III, 643; foreign bodies in, I, 437, 438, 444; excisions, trephining of, I, 463–465; balls lodged in, I, 430, 432, 435, 436, 437, 439, 441, 447, 453, 459, 460; balls extracted from, I, 430, 442, 443, 446, 452, 456, 460, 462; absence of paralysis after shot wounds of, I, 431, 442, 443, 444, 446, 447, 449, 451; tetanus, dyspnœa, pyæmia, dysphagia, costiveness, and priapism after injuries of vertebræ, I, 454. See **Vertebræ,** and **Cervical, Dorsal,** and **Lumbar.**

Spleen, ruptures of, I, 38, II, 18, 19, 26; punctured wounds of, II, 149; shot wounds of, II, 149–157, 202; III, 689; protrusion of, in penetrating wound of abdomen, II, 151; extirpation of, II, 150.

Splenic Artery, wound of, II, 159; hæmorrhage from, III, 764.

Splenitis, traumatic, II, 19, 157.

Splenotomy, II, 149, 254.

Splints, AHL'S felt, II, 822, 888; BAUER'S, II, 835; BOND'S, II, 897; DESAULT'S, III, 343; ESMARCH'S, II, 835, 888; GURDON BUCK'S, III, 348; HODGEN'S, II, 904; III, 346, 347, 348; HARLAN'S bracketed, II, 509, 517, 562; MARTIN'S, II, 822; PHYSICK'S, III, 343; SMITH'S anterior, III, 345, 346; VOLKMANN'S wire, II, 904; HEATH'S, II, 905; in excisions of the shoulder joint, II, 509, 517; in excisions of the humerus, II, 822; in shot fractures of the elbow, II, 835; in excisions at the elbow, II, 888; in fractures of the femur, III, 343.

Sprains and **Contusions,** III, 642.

Staphyloma, operations for, III, 681–683.

Staphylorraphy in wounds of upper jaw, I, 378.

Sternum, shot fractures of, I, 486, 504, 525; excisions of portions of, I, 571.

Stimulants, in shot wounds of the chest, I, 647; prior to the administration of anæsthetics, III, 889.

Stomach, rupture of, without external wound, II, 22; punctured and incised wounds of, II, 42, 56; treatment of, by ligature, II, 44; shot wounds of, II, 45–60, 154, 160, 202; III, 689; autopsies in cases of, II, 42, 48, 50, 51; escape of lumbricoid worms in wound of, II, 42.

Stomatoplasty in shot wounds of mouth, I, 370.

Strabotomy, cases of, III, 681, 682, 683.

Stricture, Traumatic, in shot wounds of urethra, II, 351–358, 365, 368, 372, 397; after laceration of urethra, III, 652.

Stromeyer's Axillary Pad in wounds of shoulder joint, II, 517.

Stumps, after amputations in thigh, by the anterior, posterior, antero-posterior, lateral, and circular methods, III, 356, and plate opposite.

Styptics, use of, in hæmorrhage, III, 812; in wounds of scalp, I, 64; of face, I, 346; injected into wounds of chest through female catheter, I, 544; danger of their falling into the pleural cavity in chest wounds, I, 550; discouraged in wounds of the abdominal parietes and abdomen, II, 9, 10, 177, 179; no reliance to be placed on the use of, II, 460.

Subclavian Artery, shot wounds of, I, 479, 521, 522, 560; hæmorrhages from, III, 764; aneurism of, I, 484; II, 621; III, 808; ligations of, II, 440, 449, 468, 632, 648, 716; III, 662; analysis of ligations of, III, 772.

Subclavian Vein, shot wound of, I, 560; hæmorrhage from, III, 816; accidentally opened while searching for artery, I, 555; rupture of, I, 527.

Sublingual Artery, wounds of, I, 347, 353, 394.

Submental Artery, injury of, III, 763; ligations of, III, 765, 772.

Subscapular Artery, injuries of, I, 351, 519, 596; II, 484; III, 764; ligations of, II, 443, 484, 585; III, 765, 776.

Subsultus Tendinum, in shot injuries of cranium, I, 160, 162, 299.

Suicides, number of cases of, during the war, III, 641.

Sunstroke, fatal case of, III, 656.

Supra-renal Capsules, shot wounds of, II, 173, 202; III, 689; autopsy in wound of, II, 173; ball encysted in II, 173.

Suprascapular Artery, wounds of, II, 490, 642; hæmorrhages from, I, 539; II, 496; III, 764; aneurism of, III, 808; ligations of, I, 538, 549; III, 765, 774.

Surgeons, duties of, as surgeons in chief: of a division, III, 906; of a brigade, III, 907; in charge of division hospital, III, 908; as attending or prescribing, III, 909; as operating, III, 909; as regimental, III, 910; as assistant regimental, III, 912.

Surgeon's Field Companion, III, 915.

Sutures, in wounds of the eyelids, I, 388; in incised wounds of the abdominal parietes, II, 4; in punctured and incised wounds of the stomach, II, 44; in shot wounds of the stomach: JOBERT'S, LEMBERT'S, II, 59; LEDRAN'S, BERTRANDI'S, II, 44; in wounds of the small intestines, II, 72, 73, 76, 112, 124, 128; PALFYN'S, BELL'S, II, 114; LEDRAN'S, BERTRANDI'S, II, 115; JOBERT'S, II, 118; LEMBERT'S, GELY'S, 119; EMMERT'S, VÉZIEN'S, II, 121; the continued, the Glover's, II, 122; BOSEMAN'S button, II, 183; HOWARD'S metallic, in excisions of the shaft of humerus, II, 820.

Symblepharon, operation for, III, 683.

Sympathetic Nerve involved in wound, II, 466.

Syndectomy, III, 682.

Talipes Equinus, resulting from shot fractures of knee joint, III, 371, 394, 395.

Target Area of different portions of the human body, III, 691.

Tarsal Bones, shot fractures of, III, 618; excisions of, III, 622, 623; amputation through, III, 628, 631, 632, 636.

Tarso-metatarsal Articulation, shot fractures of, III, 618; excisions of, III, 622.

Temperature, great diminution of, in shock attending wounds of the abdomen, II, 30; in traumatic peritonitis, II, 200.

Temporal Artery, wounds of, I, 188, 352; division of, I, 160; hæmorrhages from, I, 288, 338; III, 763; ligations of, I, 101, 215, 241, 244, 256, 310; III, 765; analysis of cases of, III, 771.

Tendons, effects of projectiles on, III, 712.

Tenotomy, III, 59.

Testes, shot wounds of, II, 405–418, 423; III, 689; excisions of, for shot injury, II, 409; III, 154; excisions of both, II, 414; suicidal tendency after loss of, II, 416; traumatic displacement of, II, 418 (note); sutures in removal of, II, 337, 410, 416; miscellaneous injuries of, I, 39; III 643, 684.

Tetanus, number of cases of, III, 818; location of injury in cases of, III, 818, 819; preponderating frequency in injuries of lower extremities, III, 818; after operations in the extremities, III, 819; ratio of mortality in, III, 819; date of appearance of, after injury, III, 819; causes of, III, 820; duration of, III, 820; treatment of, I, 454; III, 820; amputation to relieve, III, 820; tetanus among colored and white troops, III, 823; frequency of, in wounds of the nerves, III, 743; in lesions of muscular tissue, III, 713; in contusions of cranial bones, I, 122; in injuries of the face, III, 819; in injuries of the neck, III, 819; in injuries of the chest, I, 472, 635; in injuries of the abdomen, II, 14, 432, 464; in injuries of the upper extremities, II, 772, 932, 1020; III, 819; in wounds of the lower extremities, III, 35, 352, 380, 400; 416, 442, 569.

Thigh, amputations of, for shot contusions of femur, III, 172; for shot fractures of, III, 213; primary amputations of, III, 214; intermediary amputations of, III, 272; secondary amputations of, III, 304; summary of amputations in, III, 870, 871; amputations in the, followed by amputations at the hip, III, 870, 871; amputations in, compared with amputations in arm, III, 331; seat of original injury in cases of, III, 332; percentage of fatality in amputations in upper, middle, and lower thirds of, III, 333; amputations in both, III, 333; table indicating ages of patients in amputations of, III, 358; influence of size of limb on mortality rate in amputations of, III, 357; methods of amputations in, III, 355; periosteal flap operation, III, 317 (note); GRITTI'S method of, III, 357; treatment of retracted flaps in amputations of, III, 357; amputations of, for miscellaneous injuries, III, 664, 666.

Thoracentesis, for idiopathic pleurisy, I, 573; for hydrothorax, I, 573; for empyema and metastatic abscesses of lung, I, 573; summary of cases of, I, 598.

Thoracic Artery, wounds of, II, 457; hæmorrhage from, III, 764; superior thoracic, II, 817; thoracica longa, ligation of, I, 556.

Thoracic Duct, wounds of, I, 535, 634.

Thoracic Fistula in penetrating wounds of the chest, I, 630.

Thoracic Nerves, wounds of, I, 536.

Thyroid Artery, shot wounds of, I, 411; thyroid axis, hæmorrhage from, III, 764; ligations of, 765, 774; superior thyroid, shot wound of, I, 353; hæmorrhages from, III, 763; ligations of, I, 383, 387; III, 765, 771; inferior thyroid, hæmorrhages from, III, 764.

Tibia, shot contusions of, III, 428; shot fractures of, III, 432; shot perforation of, III, 722; shot fractures of, treated by conservation, III, 438, 563; hypertrophy of, III, 436; excisions of portions of, III, 445, 569, 570; excision in, a useless operation, III, 572; pseudarthrosis in excisions of, III, 572.

Tibial Arteries, wounds of, III, 764; hæmorrhages from, III, 764; *anterior:* incised wound of, III, 7; shot wounds of, III, 20, 48, 52, 55, 400; hæmorrhages from, III, 366, 378; ligations of, III, 765, 801–803; *posterior:* punctured wound of, III, 7; shot wounds of, III, 20, 47, 50, 51, 320; aneurism of, III, 7, 673, 808; ligations of, III, 765, 803–804; *anterior* and *posterior:* wounds of, III, 52; aneurism of, III, 55, 808; ligations of, III, 52, 560, 621, 765.

Tibial Nerve, *anterior:* incised wound of, III, 7; shot wounds of, III, 9, 11, 55; *posterior:* shot wounds of, III, 9, 11, 20, 54, 58; excision of portions of, III, 11, 58.

Toes, amputations of, for shot injuries, III, 628; for miscellaneous injuries and diseases, III, 664; six, III, 541.

Tongue, wounds of, I, 392; removed by ligature, I, 355.

Tonsils, excisions of, for disease, I, 415, 419.

Torpedoes, nature of injuries by, III, 706; MCCALLUM'S bridge torpedo, III, 699.

Torsion of arteries, III, 811.

Tourniquet, distribution to each soldier, III, 762; use of, III, 811; injudicious use of, resulting in necrosis, III, 676; in gangrene, III, 825; LEE and LAMBERT'S, II, 825; MOREL'S, II, 992; PETIT'S, II, 992.

Trachea, shot wounds of, I, 414; III, 688.

Tracheotomy, I, 415, 418.

Transfusion of blood, II, 642; III, 58, 811.

Transportation of Wounded: by hand litters, III, 923; by wheel litters, III, 926; by mule litters and cacolets, III, 926; by ambulance wagons, III, 944; by railway, III, 957; by water, III, 971.

Trephining, in sabre fractures of cranium, I, 22, 23, 24; for miscellaneous injuries, I, 57; for shot fractures of cranium, I, 261, 277, 317, 318, 319, 320; summary of cases of, I, 309; in injuries of spine, I, 463; missile extracted by, II, 251; bone extracted by, II, 251.

Trichiasis of the eyelid, operation for, III, 682.

Trocar, FLURANT'S, II, 385.

Tromatopnœa in wounds of chest, I, 635; for cases see I, 480, 484, 576; II, 53, 144.

Tubular Sequestra of femur, III, 224, 241.

Tympanitis, after rupture of abdominal viscera, II, 22, 26, 166, 200; in traumatic peritonitis, II, 200.

Tympanum, destroyed by shot wound, I, 384; rupture of membrane of, from propinquity to artillery fire, III, 708.

Ulna, shot contusions of, 886; shot fractures of, II, 922; shot fractures of, treated by conservation, II, 925; treated by excision of portions of, II, 934; excisions of entire, II, 860; excisions of, for miscellaneous injuries, III, 657.

Ulnar Artery, incised wound of, II, 436; III, 663; shot wounds of, II, 451, 453, 469, 470; III, 764; hæmorrhages from, III, 764; aneurism of, II, 451; III, 808; ligations of, III, 765, 784.

Ulnar Nerve, shot wounds of, II, 466.

Urethra, punctured wounds of, III, 652; other injuries of, not caused by shot, III, 375; sabre wound of, II, 374; shot wounds of, II, 351, 380 386, 404, 423; III, 689; incisions in, to prevent urinary infiltration, II, 380, 385; foreign bodies in, II, 375; instruments for removal of foreign bodies from, II, 375; foreign bodies escaping by, II, 278, 279, 280, 284, 285, 294, 379; foreign bodies extracted from, II, 352, 379; incisions in, for removal of foreign bodies, II, 378, 400; use of catheter in wounds of, II, 352; strictures of, II, 386; treatment in strictures of, II, 386; dilatation of, II, 368, 388; instruments for dilatation of, II, 388; operations on, II, 376–404.

Urethral Fistules, causes and diagnosis of, II, 360; cases of, II, 360, 369.

Urethritis, caused by frequent catheterization, II, 387.

Urethroplasty, II, 401, 402.

Urethrotomy, II, 392; internal, II, 392; instruments for internal, II, 392, 394, 395, 396; external perineal, II, 396, 397, 398.

Urinals, for urethral fistules, II, 403; GARIEL'S, II, 403.

Urinary Fistules, II, 164, 386, 387, 400; apparatus for, II, 403; PEMBERTON'S canula for, II, 403; foreign bodies escaping through, II, 265, 273, 285.

Urinary Infiltration as cause of death in shot wounds of bladder, II, 296.

Urine, *extravasation* of, as cause of death in shot wounds of bladder, II, 296; absence of extravasation in wounds of kidney or ureter, II, 193; treated by free incisions, II, 373; escape of, through wound, II, 304; *incontinence* of: in shot wounds of cranium, I, 31, 187, 252; in wounds of the bladder, II, 267, 271, 272; of the urethra, II, 353, 354, 355; *retention* of: in shot fractures of cranium, I, 37, 187, 300; in injuries of the spine, I, 425, 426, 431, 432; in wounds of the stomach, II, 42; in wounds of the intestines, II, 68.

Valgus, after excision of bones of foot, III, 623.

Varicocele, as a disability for military service, II, 422; operations for, II, 422.

Varix, aneurismal, II, 336; cases of, II, 100; III, 69, 170, 196, 373; following ligation of femoral vein, II, 354.

Veins, hæmorrhages after shot injuries of, III, 816; fatality after shot injuries of, III, 816; causes of death in injuries of, III, 816, 817; death from sudden entrance of air into, III, 817, 818; thrombosis of, III, 809; *axillary* vein, wounds of, I, 542, 555; II, 640; ligation of, I, 539, 555; *basilic,* wound of, II, 637; *brachial,* punctured wound of, II, 436; hæmorrhages from, III, 816; ligations of, II, 436, 446, 448; *cava,* bayonet wounds of, I, 468; shot wounds of, I, 520, 606; II, 139; hæmorrhages from, III, 816; *femoral,* wounds of, II, 304,

Veins– [Continued.
338, 339; III, 13, 15, 43, 44, 47, 48; hæmorrhages from, III, 757; partial division of, III, 754; primary bleeding from, III, 762; ligation of, III, 44, 47, 48, 49; III, 54; thrombi in, III, 79, 191, 590; darning needle removed from sheath of, III, 43; varix after ligation of, III, 354; *gluteal*, injury of, II, 338; hæmorrhages from, III, 816; *hæmorrhoidal*, injury of, II, 338; hæmorrhages from, III, 816; *iliac, external*, injury of, III, 191; thrombi in, III, 191; *internal*, injuries of, II, 190; III, 111; hæmorrhages from, III, 816; *intercostal*, hæmorrhage from, III, 816; *jugular, external*, injuries of, I, 407, 408, 411, 412, 491; hæmorrhages from, III, 816; *internal*, wound of, I, 421; perforation of, III, 750; hæmorrhages from, I, 420; III, 816; ligations of, for accidental cutting of, during operation, I, 392, 397; ligations of, for shot injury, I, 383; *lateral sinus*, rupture of, I, 201; *longitudinal sinus*, wounds of, I, 176, 203, 275; hæmorrhages from, III, 816; *median cephalic*, wound of, II, 536; hæmorrhages from, III, 816; *mesenteric*, hæmorrhages from, III, 816; *omo-hyoid*, shot wound of, I, 457; *parietal*, hæmorrhages from, III, 816; *popliteal*, injuries of, III, 55; hæmorrhages from, III, 816; ligations of, III, 383; *profunda femoris*, hæmorrhages from, III, 816; *saphenous* wounds of, III, 15, 55; hæmorrhages from, III, 816; ligation of, III, 52; *subclavian*, shot wound of, I, 560; hæmorrhages from, III, 816; accidentally opened while searching for artery, I, 555; ruptured, I, 527; *temporal*, hæmorrhage from, III, 816; *tibial*, punctured wound of, III, 7; shot wounds of, III, 54; wounds of veins of the pelvic cavity, II, 328.

Vena Cava, bayonet wounds of, I, 468; shot wounds of, I, 520, 606; II, 139; hæmorrhages from, III, 816.

Venesection, in penetrating wounds of the chest, I, 643–645; in wounds of the abdomen, I, 207; cases of, I, 280, 483, 485; II, 76, 138, 155.

Vertebræ, *incised* wound of, I, 425; *contusions and miscellaneous injuries* of, I, 426; *shot fractures of*, I, 430; shot fractures of cervical, I, 430; of dorsal, I, 433; of lumbar, I, 441; summary of shot fractures of, I, 452; III, 689. See **Spine.**

Vertebral Artery, shot wounds of, I, 417, 421; coat of, injured by ball lodging against it, I, 355; hæmorrhages from, III, 764.

Visceral Protrusions, after penetrating wounds of abdomen, II, 180, 182, 183, 184; excision of, II, 76; return of, II, 94.

Volar Arteries, hæmorrhages from, III, 764; ligations of, III, 765, 785, 786.

Vomiting, from the effects of anæsthetics, III, 897.

Wheel Litters, III, 926.

Windage of Balls, alleged traumatic effects of, III, 706, 707; to be dismissed from the domain of surgery, I, 344, 385; II, 28.

Wire Sutures, HOWARD'S, after excisions in shaft of humerus, II, 819; in shot fractures of femur, III, 350 (note), 351.

Worms, Lumbricoid, escape of, in wounds of abdomen, II, 42, 64, 68, 71, 94, 195.

Wounds, of entrance and exit, III, 711; caused by weapons of war, III, 685; complications of, III, 762; effects of climate on the treatment of, III, 867, 868. See **Incised, Punctured, Sabre, Bayonet,** and **Shot Wounds.**

Wrist, shot fractures of, II, 995; III, 690, 870, 871; treated by conservation, II, 996; III, 870; followed by excision, II, 999; III, 870; amputations following excisions at the, III, 870, 871; amputation at, for shot fracture, II, 1017; III, 871; artificial apparatus in fractures of, II, 998; after excisions, II, 1012, 1014, 1015; dislocations after shot fractures of, II, 1002, 1005.

LIBRARY OF THE UNIVERSITY CALIFORNIA

CORRIGENDA.

Page 2, fifteenth line, for 454, read 434.
Page 8, forty-third line, for furroughed, read *furrowed.*
Page 24, sixth line, for XI, read XII.
Page 24, ninth and tenth lines of Note 1, for A. G. D., read A. *J.* D.
Page 24, tenth line of Note 1, for 1862, read 1861.
Page 26, first line of Note 1, for shussverletzungen, read *schussverletzungen.*
Page 27, first line of Note 2, *dele* comma after *anatomie.*
Page 47, transpose Notes 2 and 3.
Page 50, TABLE IV, No. 15, for CASE 107, read CASE 110.
Page 58, TABLE VIII, No. 32, for amputation left thigh, read amp. left *leg.*
Page 62, fifty-fourth line of Note 1, for p. 16, read p. 316.
Page 63, eighth nonpareil line, for 26, read 36.
Page 63, ninth nonpareil line, for 16, read 26.
Page 82, thirty-ninth line, for meager, read *meagre.*
Page 87, fifty-fifth line, for J. F. Smith, read *H.* F. Smith.
Page 88, eighth line, *dele* the hyphen between the words forty and days.
Page 102, ninth line, for 87th New York, read *8th New Jersey.*
Page 104, description of FIG. 55, for right, read *left.*
Page 128, sixty-ninth line, for 1848, read 1851.
Page 130, fifty-sixth line, for Dominico Ludovess, read *Boasso Dominico.*
Page 136, first line, for for wounds, were, read *were for wounds,* and *dele* the comma after the word wounds.
Page 142, first line of Note 3, for Kinlock, read *Kinloch.*
Page 151, TABLE XVII, No. 9, for C. Warner, read C. *Wagner.*
Page 152, eighteenth line of Note 1, for Coxe's, read *Cox's.*
Page 153, description of FIG. 111, for *Spec.* 5614, read *Spec.* 5684.
Page 156, first line of Note 1, for p. 26, read p. 17.
Page 163, first line, *dele* the word *or* after *Williamson.*
Page 168, thirty-ninth line of Note 2, for *rézection,* read *résection.*
Page 171, first line of Note 3, for Case 340, read *Case* 338.
Page 174, first line of Note 3, for siege, read *siége.*
Page 179, Case 363, seventeenth line, for W. S. Smull, read W. *G.* Smull.
Page 181, Case 368, thirty-third line, for O. H. Hitchcock, read *H. O.* Hitchcock.
Page 186, Case 379, second line, for B. Brinton, read B. *Stone.*
Page 188, eleventh line, for McCollom, read *McCollum.*
Page 190, sixteenth line, for J. M. Gemrig, read J. *H.* Gemrig.
Page 191, thirty-eighth line, for eighty-six, read *sixty-eight.*
Page 192, twenty-fifth line, insert after Lidell a reference to Note 1.
Page 194, Case 397, third line, for W. A. Childs, read W. A. *Child.*
Page 195, Case 399, fourth line, for Brenneman, read *Breneman.*
Page 208, TABLE XXV, No. 7, for Mosely, read *Moseley.*
Page 209, seventh line, for T. Fitzgerald, read *P.* Fitzgerald.
Page 210, TABLE XXVI, No. 35, for Thomaine, read *Thomain.*
Page 214, Note 2, sixth line, for L. Johnson, read *C.* L. Johnson.
Page 215, second line of Case 429, for Jameson, read *Jamison.*
Page 220, TABLE XXX, No. 295, for L. Barney, read L. *Barnes.*
Page 222, TABLE XXX, No. 509, for N. Falsom, read N. *Folsom.*
Page 228, TABLE XXXI, No. 119, for J. M. Rizer, read *M. Rizer.*
Page 232, TABLE XXXI, No. 437, for J. F. Galloupe, read *I.* F. Galloupe.
Page 232, TABLE XXXI, No. 407, for J. H. Beach, read J. H. *Beech.*
Page 234, TABLE XXXI, No. 524, for D. S. Hayes, read D. S. *Hays.*
Page 235, TABLE XXXI, No. 663, for J. H. Beach, read J. H. *Beech.*
Page 235, TABLE XXXI, No. 684, for G. W. Simple, read G. W. *Semple.*
Page 235, TABLE XXXI, No. 703, for *Spec.* 4332, read *Spec.* 4232.
Page 236, TABLE XXXI, No. 790, for W. O. Meagher, read *W. O'Meagher.*
Page 237, TABLE XXXI, No. 854, for H. C. Messenger, 56th Ohio, read *A.* C. Messenger, 57th Ohio.
Page 239, TABLE XXXI, No. 1049, for A. Surg. M. Rizer, read Surg. M. Rizer.
Page 240, TABLE XXXI, Nos. 1116 and 1119, for Surg. C. M. Clarke, read Surg. C. M. *Clark.*
Page 240, TABLE XXXI, No. 1121, for Surg. W. R. Wray, read Surg. W. R. *Way.*
Page 240, TABLE XXXI, No. 1122, for Surg. A. M. Dougherty, read Surg. A. *N.* Dougherty.
Page 240, TABLE XXXI, No. 1140, for J. F. Kimbly, read J. *T.* Kimbly.
Page 243, forty-fourth line, for middle, read *lower.*
Page 244, descriptions of Figs. 186 and 187, for *Spec.* 1966, read *Spec.* 2966.
Page 246, TABLE XXXII, No. 140, for H. Taylor, read *J.* H. Taylor.
Page 247, TABLE XXXII, No. 173, for J. Owens, read J. *Owen.*
Page 257, TABLE XXXII, No. 1052, for *Spec.* 3882, read *Spec.* 3832.
Page 276, TABLE XXXIV, No. 95, for *Spec.* 3895, read *Spec.* 3875.
Page 276, TABLE XXXIV, No. 105, for *Spec.* 4280, read *Spec.* 4820.
Page 277, TABLE XXXIV, No. 142, for Left, read *Right.*
Page 281, TABLE XXXV, Nos. 55, 56, transpose the remarks in the third column opposite these numbers.
Page 285, TABLE XXXV, No. 390, *dele* comma after word *flaps.*
Page 286, TABLE XXXV, third column heading, for opeeators, read operators.
Page 288, Case 465, line thirty, for p. 63, read p. 53.
Page 288, Case 466, second line, for C. W. Chamberlain, read C. *N.* Chamberlain.
Page 290, Case 470, first line, for *J. N. Saxon,* read *J. N. Saxton.*
Page 295, TABLE XXXVI, No. 140, for *Spec.* 182, read *Spec.* 1882.
Page 296, TABLE XXXVI, No. 198, for Vannetta, read *Vannatta.*
Page 296, TABLE XXXVI, No. 236, for 116th Pennsylvania, read 116th *Illinois.*
Page 298, TABLE XXXVI, No. 364, for Right, read *Left.*
Page 301, TABLE XXXVI, No. 571, for Saxon, read *Saxton.*
Page 309, third line of Case 484, for Hatchett, read *Hatchitt.*
Page 313, TABLE XXXIX, No. 11, for Disch'd April 12, 1865, read Disch'd *August* 12, 1865.
Page 314, TABLE XXXIX, No. 92, for Vanvourst, read *Vanvorst.*
Page 318, line four of Case 492, for J. M. Burr, read *W. J. Burr.*
Page 336, TABLE XLVIII, 7th line, for 1739, read 1743.
Page 337, forty-ninth nonpareil line, for 1876, read 1871, and for B. XXIII, read B. XXIV.
Page 348, second line of Note 1, for Schrady, read *Shrady.*
Page 351, second line of Case 497, for L. W. Reed, read L. W. *Read.*
Page 372, descriptions of Figs. 223 and 224, for Schenk, read *Schenck.*
Page 373, thirteenth line, for 272, read 372.
Page 449, TABLE LXIII, No. 1, third column, strike out the words *leg useful.*
Page 458, first line of Note 2, for middle, read *upper.*
Page 459, TABLE LXV, No. 47, for large portion of tibia and fibula, read *small portion of fibula above malleolus.*
Page 464, sixth line of Case 727, for *Spec.* 4081, read *Spec.* 4018.
Page 477, TABLE LXVIII, No. 999, for Walters, read *Waters.*
Page 586, for Case 385, read Case 835.
Page 658, description of Fig. 368, for fibula, read *tibia.*
Page 838, sixteenth line, for Feburary, read *February.*
